

# [MS-DFSNM]: Distributed File System (DFS): Namespace Management Protocol

---

## Intellectual Property Rights Notice for Open Specifications Documentation

- **Technical Documentation.** Microsoft publishes Open Specifications documentation for protocols, file formats, languages, standards as well as overviews of the interaction among each of these technologies.
- **Copyrights.** This documentation is covered by Microsoft copyrights. Regardless of any other terms that are contained in the terms of use for the Microsoft website that hosts this documentation, you may make copies of it in order to develop implementations of the technologies described in the Open Specifications and may distribute portions of it in your implementations using these technologies or your documentation as necessary to properly document the implementation. You may also distribute in your implementation, with or without modification, any schema, IDL's, or code samples that are included in the documentation. This permission also applies to any documents that are referenced in the Open Specifications.
- **No Trade Secrets.** Microsoft does not claim any trade secret rights in this documentation.
- **Patents.** Microsoft has patents that may cover your implementations of the technologies described in the Open Specifications. Neither this notice nor Microsoft's delivery of the documentation grants any licenses under those or any other Microsoft patents. However, a given Open Specification may be covered by Microsoft [Open Specification Promise](#) or the [Community Promise](#). If you would prefer a written license, or if the technologies described in the Open Specifications are not covered by the Open Specifications Promise or Community Promise, as applicable, patent licenses are available by contacting [iplg@microsoft.com](mailto:iplg@microsoft.com).
- **Trademarks.** The names of companies and products contained in this documentation may be covered by trademarks or similar intellectual property rights. This notice does not grant any licenses under those rights. For a list of Microsoft trademarks, visit [www.microsoft.com/trademarks](http://www.microsoft.com/trademarks).
- **Fictitious Names.** The example companies, organizations, products, domain names, email addresses, logos, people, places, and events depicted in this documentation are fictitious. No association with any real company, organization, product, domain name, email address, logo, person, place, or event is intended or should be inferred.

**Reservation of Rights.** All other rights are reserved, and this notice does not grant any rights other than specifically described above, whether by implication, estoppel, or otherwise.

**Tools.** The Open Specifications do not require the use of Microsoft programming tools or programming environments in order for you to develop an implementation. If you have access to Microsoft programming tools and environments you are free to take advantage of them. Certain Open Specifications are intended for use in conjunction with publicly available standard specifications and network programming art, and assumes that the reader either is familiar with the aforementioned material or has immediate access to it.

## Revision Summary

Date	Revision History	Revision Class	Comments
07/20/2007	0.1	Major	MCPP Milestone 5 Initial Availability
09/28/2007	0.2	Minor	Updated the technical content.
10/23/2007	0.2.1	Editorial	Revised and edited the technical content.

01/16/2009	9.0	Major	Updated and revised the technical content.
02/27/2009	10.0	Major	Updated and revised the technical content.
04/10/2009	10.0.1	Editorial	Revised and edited the technical content.
05/22/2009	10.0.2	Editorial	Revised and edited the technical content.
07/02/2009	11.0	Major	Updated and revised the technical content.
08/14/2009	12.0	Major	Updated and revised the technical content.
09/25/2009	13.0	Major	Updated and revised the technical content.
11/06/2009	14.0	Major	Updated and revised the technical content.
12/18/2009	15.0	Major	Updated and revised the technical content.
01/29/2010	16.0	Major	Updated and revised the technical content.
03/12/2010	16.0.1	Editorial	Revised and edited the technical content.
04/23/2010	17.0	Major	Updated and revised the technical content.
06/04/2010	18.0	Major	Updated and revised the technical content.
07/16/2010	19.0	Major	Significantly changed the technical content.

<b>Date</b>	<b>Revision History</b>	<b>Revision Class</b>	<b>Comments</b>
08/27/2010	20.0	Major	Significantly changed the technical content.
10/08/2010	20.0	No change	No changes to the meaning, language, or formatting of the technical content.
11/19/2010	21.0	Major	Significantly changed the technical content.
01/07/2011	21.0	No change	No changes to the meaning, language, or formatting of the technical content.
02/11/2011	22.0	Major	Significantly changed the technical content.
03/25/2011	22.1	Minor	Clarified the meaning of the technical content.
05/06/2011	22.1	No change	No changes to the meaning, language, or formatting of the technical content.
06/17/2011	22.2	Minor	Clarified the meaning of the technical content.
09/23/2011	22.2	No change	No changes to the meaning, language, or formatting of the technical content.
12/16/2011	23.0	Major	Significantly changed the technical content.
03/30/2012	24.0	Major	Significantly changed the technical content.
07/12/2012	25.0	Major	Significantly changed the technical content.
10/25/2012	25.0	No change	No changes to the meaning, language, or formatting of the technical content.
01/31/2013	25.0	No change	No changes to the meaning, language, or formatting of the technical content.
08/08/2013	26.0	Major	Significantly changed the technical content.
11/14/2013	26.0	No change	No changes to the meaning, language, or formatting of the technical content.
02/13/2014	27.0	Major	Significantly changed the technical content.

# 1 Introduction

The Distributed File System (DFS): Namespace Management Protocol provides a **remote procedure call (RPC)** interface for administering **DFS** configurations. The client is an application that issues method calls on the RPC interface to administer DFS. The server is a DFS service that implements support for this RPC interface for administering DFS.

Sections 1.8, 2, and 3 of this specification are normative and can contain the terms MAY, SHOULD, MUST, MUST NOT, and SHOULD NOT as defined in RFC 2119. Sections 1.5 and 1.9 are also normative but cannot contain those terms. All other sections and examples in this specification are informative.

## 1.1 Glossary

The following terms are defined in [\[MS-GLOS\]](#):

- 8.3 name**
- access control list (ACL)**
- Active Directory**
- Active Directory Domain Services (AD DS)**
- authentication level**
- binary large object (BLOB)**
- Coordinated Universal Time (UTC)**
- directory object**
- directory service (DS)**
- Distributed File System (DFS)**
- Distributed File System (DFS) client**
- Distributed File System (DFS) client target failback**
- Distributed File System (DFS) client target failover**
- Distributed File System (DFS) in-site referral mode**
- Distributed File System (DFS) interlink**
- Distributed File System (DFS) link**
- Distributed File System (DFS) link target**
- Distributed File System (DFS) metadata**
- Distributed File System (DFS) namespace**
- Distributed File System (DFS) path**
- Distributed File System (DFS) referral**
- Distributed File System (DFS) referral site costing**
- Distributed File System (DFS) root**
- Distributed File System (DFS) root scalability mode**
- Distributed File System (DFS) root target**
- DN**
- domain**
- domain controller (DC)**
- dynamic object**
- endpoint**
- file system**
- FILETIME**
- forest**
- globally unique identifier (GUID)**
- GUIDString**
- Interface Definition Language (IDL)**
- Lightweight Directory Access Protocol (LDAP)**

little-endian  
member server  
Microsoft Interface Definition Language (MIDL)  
NetBIOS name  
object  
opnum  
primary domain controller (PDC)  
relative distinguished name (RDN)  
remote procedure call (RPC)  
reparse point  
RPC protocol sequence  
RPC transport  
Server Message Block (SMB)  
share  
site  
system access control list (SACL)  
Unicode  
Universal Naming Convention (UNC)  
universally unique identifier (UUID)  
well-known endpoint

The following terms are specific to this document:

**Access Based Directory Enumeration (ABDE) mode:** A mode where the server filters directory entries according to the access permissions of the client. In a **DFS** scenario, **ABDE** is enabled on the **DFS root target share** to prevent a user from seeing another user's home directory. The **DFS namespace** administrator can create a **DFS link** for a user (or user group), and a user is granted appropriate rights to the **DFS link**.

**clustered DFS namespace:** A **stand-alone DFS namespace** that is hosted on a file server cluster.

**Distributed File System (DFS) namespace name:** The second pathname component of a **DFS path**. For example, in the **DFS path** \\MyDomain\MyDfs\MyDir, the **DFS namespace name** is MyDfs.

**Distributed File System (DFS) server:** A server computer running the **DFS** service that responds to **DFS referral** requests, as specified in [\[MS-DFSC\]](#), as well as to the DFS: Namespace Management Protocol. Also used interchangeably to refer to the **DFS** service itself.

**Distributed File System (DFS) target:** Either a **DFS root target** server or a **DFS link target** server.

**domain-based DFS namespace:** A **DFS namespace** that has configuration information stored in domain services. The **DFS namespace** may span a distributed system that is organized hierarchically into logical domains. The path to access a **domain-based DFS namespace** starts with the host domain name. A **domain-based DFS namespace** can have multiple **DFS root targets**, which offers high availability and load sharing at the **DFS root** level.

**domainv1-based DFS namespace:** A type of **domain-based DFS namespace** that has its **DFS metadata** stored in directory services as an ftDfs type **object**.

**domainv2-based DFS namespace:** A type of **domain-based DFS namespace** that has its **DFS metadata** stored in the form of individual **LDAP** entries, with one **LDAP** entry per **DFS link**. Each **LDAP** entry contains the **DFS metadata** (such as targets, properties, and other information) that corresponds to that entity.

**host name:** Name of a computer used for identification and access purposes by humans and other computers in a network.

**object store:** A system that provides the ability to create, query, modify, or apply policy to a local resource. The object store is typically backed by a **file system**.

**share name:** The name of a **share**.

**site cost:** An **Active Directory Domain Services** administrator-defined numeric value meant to indicate the bandwidth or actual monetary cost of transmitting data between two sites. Only a comparison between two **site cost** values is meaningful, with a lower site cost preferred to a higher site cost.

**stand-alone DFS namespace:** A **DFS namespace** that has **DFS metadata** stored locally on the host server. The path to access the **DFS root** or a **DFS link** starts with the **DFS root target host name**. A **stand-alone DFS namespace** has only one **DFS root target**. Stand-alone **DFS roots** are not fault-tolerant; when the **DFS root target** is unavailable, the entire **DFS namespace** is inaccessible. Stand-alone **DFS roots** can be made fault-tolerant by being created on clustered file servers.

**MAY, SHOULD, MUST, SHOULD NOT, MUST NOT:** These terms (in all caps) are used as described in [\[RFC2119\]](#). All statements of optional behavior use either MAY, SHOULD, or SHOULD NOT.

## 1.2 References

References to Microsoft Open Specifications documentation do not include a publishing year because links are to the latest version of the documents, which are updated frequently. References to other documents include a publishing year when one is available.

A reference marked "(Archived)" means that the reference document was either retired and is no longer being maintained or was replaced with a new document that provides current implementation details. We archive our documents online [\[Windows Protocol\]](#).

### 1.2.1 Normative References

We conduct frequent surveys of the normative references to assure their continued availability. If you have any issue with finding a normative reference, please contact [dochelp@microsoft.com](mailto:dochelp@microsoft.com). We will assist you in finding the relevant information.

## 1.3 Overview

The DFS: Namespace Management Protocol is one of a collection of protocols that group **shares** that are located on different servers by combining various storage media into a single logical namespace. The **DFS namespace** is a virtual view of the share. When a user views the namespace, the directories and files in it appear to reside on a single share. Users can navigate the namespace

without needing to know the server names or shares hosting the data. DFS also provides redundancy of namespace service.

Access to a DFS namespace requires the **DFS client**. The DFS client uses the **DFS Referral Protocol**, as specified in [\[MS-DFSC\]](#), to ascertain the existence of the DFS namespace and to determine the shares to access on servers that participate in the DFS namespace. The DFS Referral Protocol navigates through the DFS namespace by appropriately issuing referral requests to a **domain controller (DC)** or to a **DFS root target** server to resolve the original path to a share on a server that contains the data being accessed. For more information on DFS and the DFS client, see [\[MSDFS\]](#). For more information on how the DFS Referral Protocol operates within the context of the **Server Message Block (SMB)** Protocol, as specified in [\[MS-SMB\]](#), which is the transport for DFS referrals, see [\[MS-DFSC\]](#) section 2.

DFS namespace information, such as name, **DFS link name**, **DFS link target**, and so on, is stored in the **DFS metadata** of the namespace. Depending on where the DFS metadata is stored, the DFS namespace is "domain-based" or "stand-alone".

- **Domain-Based DFS Namespace:** A well-known container in the **domain** directory, known as the DFS configuration container, holds the DFS metadata for a domain-based DFS namespace. An **object** exists for each domain-based DFS namespace in the DFS configuration container. DFS metadata of a domain-based DFS namespace is stored as a **binary large object (BLOB)** in an attribute of the DFS namespace object. A domain-based DFS namespace can have multiple DFS root targets, which offer high availability and load sharing at the DFS root level. The **DFS root** name of a domain-based DFS namespace has the domain as its first component. A DFS client issues a referral request to a DC in order to identify the DFS root targets of the DFS namespace.
- **Stand-Alone DFS Namespace:** DFS metadata is stored in an implementation-specific format on the DFS root target server itself. A stand-alone DFS namespace supports only one DFS root target. The DFS root name of a stand-alone DFS namespace has a **host name** as its first component. A DFS client issues referral requests to the DFS root target server to access the DFS namespace. A stand-alone DFS namespace may be clustered to provide high availability of the DFS namespace. <1> The server hosting a stand-alone DFS namespace can be promoted to a Domain Controller, but the namespace cannot be converted to a domain-based namespace, and it will continue as a stand-alone namespace.

A server cannot host both domain-based and stand-alone namespace roots with the same name.

The DFS: Namespace Management Protocol is used to configure DFS services. This protocol is used primarily by administrative applications that run on client computers to connect and configure **Distributed File System (DFS) servers**. It consists of the RPC methods that can be issued from an administrative client computer to the protocol server on a DC or a Distributed File System (DFS) root target server. An administrator can use this protocol to perform various Distributed File System (DFS) namespace administration operations, such as creating or deleting a DFS namespace, adding or removing DFS root targets, adding or removing DFS links, and adding or removing targets to an existing link. The DFS: Namespace Management Protocol includes the following:

- Eleven basic methods for configuring stand-alone DFS namespaces and domain-based DFS namespaces, as specified in section [3.1.4.1](#).
- Four methods that support extended access to configurations of a DFS namespace, as specified in section [3.1.4.2](#).
- Three methods for configuring root targets in a **domainv1-based DFS namespace**, as specified in section [3.1.4.3](#).
- Three methods for configuring a stand-alone DFS namespace, as specified in section [3.1.4.4](#).

- Two methods relating to the association between a DFS server and the DC used by a domain-based DFS namespace, as specified in section [3.1.4.5](#).

Much of the configuration information that is communicated through this protocol is marshaled through two unions: [DFS\\_INFO\\_STRUCT](#) and [DFS\\_INFO\\_ENUM\\_STRUCT](#). The usage model of these unions is for the client to specify a *Level* parameter to determine which union case to use. Each level corresponds to a specific `DFS_INFO_n` structure, where *n* is the level number. Arrays of `DFS_INFO_n` structures are marshaled using `DFS_INFO_n_CONTAINER` structures. Levels 1, 2, 3, 4, 5, 6, 8, and 9 are common, and are shared across both the **DFS\_INFO\_STRUCT** and **DFS\_INFO\_ENUM\_STRUCT** unions. Levels 7, 50, 100, 101, 102, 103, 104, 105, 106, 107, and 150 are unique to the **DFS\_INFO\_STRUCT** union, and Levels 200 and 300 are unique to the **DFS\_INFO\_ENUM\_STRUCT** union.

While a number of methods use the common configuration information structures, not all methods support all levels. The following table lists the levels used in the **DFS\_INFO\_STRUCT** and **DFS\_INFO\_ENUM\_STRUCT** unions, their singleton and array structures, and the methods with which the level can be used.

Level	Structure	Array structure	NetrDfs GetInfo	NetrDfs Enum	NetrDfs SetInfo	NetrDfs SetInfo2	NetrDfs EnumEx
1	DFS_INFO_1	DFS_INFO_1_CONTAINER	X	X			X
2	DFS_INFO_2	DFS_INFO_2_CONTAINER	X	X			X
3	DFS_INFO_3	DFS_INFO_3_CONTAINER	X	X			X
4	DFS_INFO_4	DFS_INFO_4_CONTAINER	X	X			X
5	DFS_INFO_5	DFS_INFO_5_CONTAINER	X	X			X
6	DFS_INFO_6	DFS_INFO_6_CONTAINER	X	X			X
7	DFS_INFO_7	N/A	X				
8	DFS_INFO_8	DFS_INFO_8_CONTAINER	X	X			X
9	DFS_INFO_9	DFS_INFO_9_CONTAINER	X	X			X
50	DFS_INFO_50	N/A	X				
100	DFS_INFO_100	N/A	X		X	X	
101	DFS_INFO_101	N/A			X	X	
102	DFS_INFO_102	N/A			X	X	
103	DFS_INFO_103	N/A			X	X	

Level	Structure	Array structure	NetrDfs GetInfo	NetrDfs Enum	NetrDfs SetInfo	NetrDfs SetInfo2	NetrDfs EnumEx
104	DFS_INFO_104	N/A			X	X	
105	DFS_INFO_105	N/A			X	X	
106	DFS_INFO_106	N/A			X	X	
107	DFS_INFO_107	N/A			X	X	
150	DFS_INFO_150	N/A	X		X	X	
200	DFS_INFO_200	DFS_INFO_200_CONTAINER					X
300	DFS_INFO_300	DFS_INFO_300_CONTAINER		X			X

## 1.4 Relationship to Other Protocols

The DFS: Namespace Management Protocol is used to configure and administer DFS namespaces. It depends on RPC for its transport.

The DFS: Namespace Management Protocol is the recommended method of performing DFS namespace operations. This protocol is used in many operations (for example, creating a new DFS namespace or adding or removing DFS links or DFS link targets). All of these operations require updating the DFS metadata of a DFS namespace.

The DFS Referral Protocol, as specified in [\[MS-DFSC\]](#), accesses the DFS metadata of a DFS namespace for providing DFS referral responses. The DFS clients issue DFS referral requests to verify the existence of a DFS namespace and to identify the targets of a **DFS path**, as specified in [\[MS-DFSC\]](#). The DFS Referral Protocol permits DFS clients to navigate the DFS namespace and to locate the share on a server that contains the required data. The DFS Referral Protocol is implemented as a set of SMB Protocol extensions to commands, such as TRANS2\_GET\_DFS\_REFERRAL to request DFS referrals from DCs, as specified in [\[MS-SMB\]](#).

After a DFS path is resolved to a **DFS target** by using the DFS Referral Protocol, a client accesses resources on the server identified by the DFS target by using a resource access protocol, such as the following:

- SMB, as specified in [\[MS-SMB\]](#).
- SMB2, as specified in [\[MS-SMB2\]](#).
- Network File System (NFS), as specified in [\[RFC3530\]](#).
- Network Control Protocol (NCP), as specified in [\[NOVELL\]](#).
- Web Distributed Authoring and Versioning (WebDAV), as specified in [\[RFC2518\]](#).

A resource access protocol implementation uses name resolution protocols, such as DNS (as specified in [\[RFC1034\]](#)) or SLP (as specified in [\[RFC2165\]](#)), to resolve DFS target host names.

The DFS metadata of a domain-based DFS namespace is stored in Directory Services. A DFS server uses the **Lightweight Directory Access Protocol (LDAP)**, as specified in [\[RFC2251\]](#), to access

the DFS metadata from the DS for use with both the DFS: Namespace Management Protocol and the DFS Referral Protocol.

## 1.5 Prerequisites/Preconditions

The DFS: Namespace Management Protocol is an RPC interface and, as a result, has prerequisites common to RPC interfaces. These prerequisites are specified in [\[MS-RPCE\]](#).

Before a client invokes this protocol, it must obtain the name of a server that supports DFS services and RPC.

To avoid conflicts between updates to DFS metadata:

- At most, one client can modify the metadata for a given DFS namespace at a time.
- A domain-based DFS server must perform all DFS metadata updates to the **primary domain controller (PDC)** independently of the **DFS root scalability mode** setting of the DFS namespace. <2>

## 1.6 Applicability Statement

The DFS: Namespace Management Protocol is appropriate for managing a domain-based DFS namespace or a stand-alone DFS namespace.

## 1.7 Versioning and Capability Negotiation

This document covers versioning issues in the following areas:

- Supported transports: The DFS: Namespace Management Protocol uses RPC over SMB1.x or SMB2 as its only supported transport. For more information on transport specifications, see section [2.1](#).
- Protocol versions: The RPC interface for this protocol has a single version number of 3.0. This protocol can be extended without altering the version number by adding RPC methods to the interface, with **opnums** positioned numerically beyond those defined in this specification. A client determines whether such methods are supported by attempting to invoke the method; if the method is not supported, the RPC server returns an "opnum out of range" error. RPC versioning and capacity negotiation in this situation is specified in [\[C706\]](#) and [\[MS-RPCE\]](#). <3>
- Security and authentication methods: As specified in [\[MS-RPCE\]](#).
- Capability negotiation: None.

## 1.8 Vendor-Extensible Fields

None.

## 1.9 Standards Assignments

No standards assignments have been received for the RPC interface **UUID** or for the well-known pipe name described in this document. All values used in these extensions are in private ranges, as specified in [\[MS-RPCE\]](#) and [\[MS-SMB\]](#).

## 2 Messages

### 2.1 Transport

The DFS root target MUST reside on a server that is accessible through SMB (as specified in [\[MS-SMB\]](#)) or SMB2 (as specified in [\[MS-SMB2\]](#)). A link target can reside on a server that is accessible through any resource access protocol for which appropriate client-side software exists.

The DFS: Namespace Management Protocol uses RPC over SMB, as specified in [\[MS-RPCE\]](#).

This protocol uses a **well-known endpoint**, `\\PIPE\NETDFS`, for RPC over SMB. The RPC interface uses transport-level authentication, as specified in [\[MS-RPCE\]](#). **DFS** is not directly involved in authentication; however, the DFS service MUST verify whether the user has administrator privileges to the namespace. The authenticated RPC interface allows RPC to negotiate the use of authentication and the **authentication level** on behalf of the client and server, as specified in [\[MS-RPCE\]](#) section 3.3.1.5.2. The server MUST find the security context indicated by the `auth_context_id` in the `sec_trailer` of the request, and it MUST ask the security provider that created the security context to retrieve the client identity.

This protocol MUST use the universally unique identifier (UUID) 4FC742E0-4A10-11CF-8273-00AA004AE673. The RPC version number is 3.0.

This protocol allows any user to establish a connection to a DFS server. It uses the underlying RPC protocol to retrieve the identity of the caller that made the request, as specified in [\[MS-RPCE\]](#) section 3.3.3.4.3. The RPC server SHOULD use this identity to verify method-specific access.

### 2.2 Common Data Types

#### 2.2.1 Common Conventions

Unless otherwise specified, all strings in this protocol are null-terminated strings of UTF-16, as specified in [\[UNICODE\]](#) characters. Backslashes (`\`) in string descriptions are literal characters.

Constructs of the form "`<value>`" in strings are placeholders to be replaced with client-specified or server-specified values. For example, the string description "`\\<servername>\<share>`" would take the form "`\\myserver\myshare`" when populated with the values "myserver" for the `<servername>` placeholder and "myshare" for the `<share>` placeholder.

A number of string formats are common to many of the data types and methods in this protocol. To avoid repetition, this section describes the specific formats.

##### 2.2.1.1 Host Name

A host name represents the host name of a server or the domain name of a domain hosting resource as specified in [\[MS-DTYP\]](#) section 2.2.57.

##### 2.2.1.2 Share Name

Unless specified otherwise, a **share name** is a null-terminated **Unicode** character string whose format depends on the actual file server protocol used to access the share as specified in [\[MS-DTYP\]](#) section 2.2.57.

### 2.2.1.3 Domain Name

Unless specified otherwise, a domain name is a null-terminated Unicode character string consisting of the name of a Directory Service domain. For more details, see [\[MS-DTYP\]](#) section 2.2.57.

### 2.2.1.4 UNC Path

A [Universal Naming Convention \(UNC\)](#) path, as specified in [\[MS-DTYP\]](#) section 2.2.57, can be used to access network resources.

### 2.2.1.5 DFS Root

A DFS root has one of the following **UNC** path formats.

```
\\<ServerName>\<DFSName>  
\\<DomainName>\<DFSName>
```

where:

- <ServerName> is the host name (as specified in section [2.2.1.1](#)) of a DFS root target (as specified in section [2.2.1.7](#)) of the DFS namespace.
- <DomainName> is the domain name (as specified in section [2.2.1.3](#)) of the domain hosting the domain-based DFS namespace.
- <DFSName> is the **DFS namespace name**. A stand-alone DFS namespace can be referred to only by the first format. A domain-based DFS namespace can be referred to in either format, with the second format preferred.

### 2.2.1.6 DFS Link

A DFS link has one of the following UNC path formats.

```
\\<ServerName>\<DFSName>\<LinkPath>  
\\<DomainName>\<DFSName>\<LinkPath>
```

where:

- <ServerName> is the host name of a DFS root target of the DFS namespace.
- <DomainName> is the domain name of the domain hosting the domain-based DFS namespace.
- <DFSName> is the DFS namespace name.
- <LinkPath> is the path of the DFS link relative to the DFS root target share. A stand-alone DFS namespace can be referred to only by the first format. A domain-based DFS namespace can be referred to in either format, with the second format preferred.

### 2.2.1.7 DFS Root Target

A DFS root target is a UNC path with the following format.

```
\\<servername>\<sharename>
```

where:

- <servername> is the host name of a DFS root target server.
- <sharename> is the share name corresponding to a DFS namespace on the DFS root target server.

### 2.2.1.8 DFS Link Target

A DFS link target is any UNC path that resolves to a directory.

### 2.2.1.9 DFS Target

A DFS target is either a DFS root target or a DFS link target.

## 2.2.2 Common Data Types

In addition to RPC base types and definitions, as specified in [\[C706\]](#) and [\[MS-RPCE\]](#), the following sections use the definitions of DWORD, **GUID**, and WCHAR, as specified in [\[MS-DTYP\]](#) DWORD section [2.2.9](#), GUID section [2.3.4.2](#), and WCHAR section [2.2.60](#). Any remaining data types in this section are defined in the **Interface Definition Language (IDL)** specification for this RPC interface.

This protocol MUST enable the ms\_union extension as specified in [\[MS-RPCE\]](#), section [2.2.4](#).

### 2.2.2.1 NET\_API\_STATUS

The **NET\_API\_STATUS** type is an unsigned, 32-bit integer value representing the return code from an RPC method.

This type is declared as follows:

```
typedef DWORD NET_API_STATUS;
```

This protocol uses Microsoft Win32 error codes. The values are taken from the Windows error number space, as specified in [\[MS-ERREF\]](#). Vendors SHOULD reuse those values with their indicated meanings. Choosing any other value creates the risk of collisions in the future.

### 2.2.2.2 NETDFS\_SERVER\_OR\_DOMAIN\_HANDLE

The **NETDFS\_SERVER\_OR\_DOMAIN\_HANDLE** is a pointer to a Unicode string representing a host name for an RPC method.

This type is declared as follows:

```
typedef WCHAR* NETDFS_SERVER_OR_DOMAIN_HANDLE;
```

### 2.2.2.3 DFS\_INFO\_STRUCT

The **DFS\_INFO\_STRUCT** union relates to the [NetrDfsGetInfo](#), [NetrDfsSetInfo](#), and [NetrDfsSetInfo2](#) methods when used to retrieve or set the configuration of the DFS server. The usage model of this union is for the client to specify a *Level/* parameter to determine which case of the **DFS\_INFO\_STRUCT** to use.

The **DFS\_INFO\_STRUCT** union has the following format.

```
typedef
[switch_type(unsigned long)]
union _DFS_INFO_STRUCT {
    [case(1)]
        DFS_INFO_1* DfsInfo1;
    [case(2)]
        DFS_INFO_2* DfsInfo2;
    [case(3)]
        DFS_INFO_3* DfsInfo3;
    [case(4)]
        DFS_INFO_4* DfsInfo4;
    [case(5)]
        DFS_INFO_5* DfsInfo5;
    [case(6)]
        DFS_INFO_6* DfsInfo6;
    [case(7)]
        DFS_INFO_7* DfsInfo7;
    [case(8)]
        DFS_INFO_8* DfsInfo8;
    [case(9)]
        DFS_INFO_9* DfsInfo9;
    [case(50)]
        DFS_INFO_50* DfsInfo50;
    [case(100)]
        DFS_INFO_100* DfsInfo100;
    [case(101)]
        DFS_INFO_101* DfsInfo101;
    [case(102)]
        DFS_INFO_102* DfsInfo102;
    [case(103)]
        DFS_INFO_103* DfsInfo103;
    [case(104)]
        DFS_INFO_104* DfsInfo104;
    [case(105)]
        DFS_INFO_105* DfsInfo105;
    [case(106)]
        DFS_INFO_106* DfsInfo106;
    [case(107)]
        DFS_INFO_107* DfsInfo107;
    [case(150)]
        DFS_INFO_150* DfsInfo150;
    [default]
        ;
} DFS_INFO_STRUCT;
```

**DfsInfo1:** The [DFS\\_INFO\\_1](#) structure contains the name of a DFS root or DFS link. For more information on the specifications, see section [2.2.3.1](#).

**DfsInfo2:** The [DFS\\_INFO\\_2](#) structure contains information for a DFS root or DFS link. For more information on specifications, see section [2.2.3.2](#).

- DfsInfo3:** The [DFS\\_INFO\\_3](#) structure contains information for a DFS root or DFS link. For more information on specifications, see section [2.2.3.3](#).
- DfsInfo4:** The [DFS\\_INFO\\_4](#) structure contains information for a DFS root or DFS link. For more information on specifications, see section [2.2.3.4](#).
- DfsInfo5:** The [DFS\\_INFO\\_5](#) structure contains information for a DFS root or DFS link. For more information on specifications, see section [2.2.3.5](#).
- DfsInfo6:** The [DFS\\_INFO\\_6](#) structure contains information for a DFS root or DFS link. For more information on specifications, see section [2.2.3.6](#).
- DfsInfo7:** The [DFS\\_INFO\\_7](#) structure contains information about a DFS root or DFS link. For more information on specifications, see section [2.2.3.7](#).
- DfsInfo8:** The [DFS\\_INFO\\_8](#) structure contains information about a DFS root or DFS link. For more information on specifications, see section [2.2.3.8](#).
- DfsInfo9:** The [DFS\\_INFO\\_9](#) structure contains information about a DFS root or DFS link. For more information on specifications, see section [2.2.3.9](#).
- DfsInfo50:** The [DFS\\_INFO\\_50](#) structure contains information about a DFS root or DFS link. For more information on specifications, see section [2.2.3.10](#).
- DfsInfo100:** The [DFS\\_INFO\\_100](#) structure contains a comment associated with a DFS root or DFS link. For more information on specifications, see section [2.2.5.1](#).
- DfsInfo101:** The [DFS\\_INFO\\_101](#) structure describes the storage state on a DFS root, DFS link, DFS root target, or DFS link target. For more information on specifications, see section [2.2.4.1](#).
- DfsInfo102:** The [DFS\\_INFO\\_102](#) structure contains a time-out value for a DFS root or DFS link. For more information on specifications, see section [2.2.4.2](#).
- DfsInfo103:** The [DFS\\_INFO\\_103](#) structure contains properties that set specific behaviors for a DFS root or DFS link. For more information on specifications, see section [2.2.4.3](#).
- DfsInfo104:** The [DFS\\_INFO\\_104](#) structure contains the priority of a DFS root target or DFS link target. For more information on specifications, see section [2.2.4.4](#).
- DfsInfo105:** The [DFS\\_INFO\\_105](#) structure contains information about a DFS root or DFS link, including comment, state, time-out, and DFS behaviors that property flags specify. For more information on specifications, see section [2.2.4.5](#).
- DfsInfo106:** The [DFS\\_INFO\\_106](#) structure contains the storage state and priority for a DFS root target or DFS link target. For more information on specifications, see section [2.2.4.6](#).
- DfsInfo107:** The [DFS\\_INFO\\_107](#) structure contains the storage state and priority for a DFS root target or DFS link target. For more information on specifications, see section [2.2.4.7](#).
- DfsInfo150:** The [DFS\\_INFO\\_150](#) structure contains the self-relative security descriptor associated with the DFS link. For more information on specifications, see section [2.2.5.2](#).

#### 2.2.2.4 DFS\_INFO\_ENUM\_STRUCT

The **DFS\_INFO\_ENUM\_STRUCT** union relates to the [NetrDfsEnum](#) and [NetrDfsEnumEx](#) methods when used to enumerate the configuration of the DFS server.

The **DFS\_INFO\_ENUM\_STRUCT** union structure has the following format.

```
typedef struct _DFS_INFO_ENUM_STRUCT {
    DWORD Level;
    [switch_is(Level)] union {
        [case(1)]
            DFS_INFO_1_CONTAINER* DfsInfo1Container;
        [case(2)]
            DFS_INFO_2_CONTAINER* DfsInfo2Container;
        [case(3)]
            DFS_INFO_3_CONTAINER* DfsInfo3Container;
        [case(4)]
            DFS_INFO_4_CONTAINER* DfsInfo4Container;
        [case(5)]
            DFS_INFO_5_CONTAINER* DfsInfo5Container;
        [case(6)]
            DFS_INFO_6_CONTAINER* DfsInfo6Container;
        [case(8)]
            DFS_INFO_8_CONTAINER* DfsInfo8Container;
        [case(9)]
            DFS_INFO_9_CONTAINER* DfsInfo9Container;
        [case(200)]
            DFS_INFO_200_CONTAINER* DfsInfo200Container;
        [case(300)]
            DFS_INFO_300_CONTAINER* DfsInfo300Container;
    } DfsInfoContainer;
} DFS_INFO_ENUM_STRUCT;
```

**Level:** Specifies the case of the **DfsInfoContainer** union.

**DfsInfoContainer:** Union of the possible enumeration containers.

**DfsInfo1Container:** The [DFS\\_INFO\\_1\\_CONTAINER](#) structure contains an array of the names of DFS roots or DFS links. For more information, see section [2.2.6.1](#).

**DfsInfo2Container:** The [DFS\\_INFO\\_2\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.2](#).

**DfsInfo3Container:** The [DFS\\_INFO\\_3\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.3](#).

**DfsInfo4Container:** The [DFS\\_INFO\\_4\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.4](#).

**DfsInfo5Container:** The [DFS\\_INFO\\_5\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.5](#).

**DfsInfo6Container:** The [DFS\\_INFO\\_6\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.6](#).

**DfsInfo8Container:** The [DFS\\_INFO\\_8\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.7](#).

**DfsInfo9Container:** The [DFS\\_INFO\\_9\\_CONTAINER](#) structure contains an array of information for DFS roots or DFS links. For more information, see section [2.2.6.8](#).

**DfsInfo200Container:** The [DFS\\_INFO\\_200\\_CONTAINER](#) structure contains an array of the names of domain-based DFS namespaces in a domain-based DFS. For more information, see section [2.2.6.9](#).

**DfsInfo300Container:** The [DFS\\_INFO\\_300\\_CONTAINER](#) structure contains an array of the DFS roots hosted on a server. For more information, see section [2.2.6.10](#).

### 2.2.2.5 DFS\_STORAGE\_INFO

The **DFS\_STORAGE\_INFO** structure relates to the [NetrDfsEnum](#), [NetrDfsEnumEx](#), and [NetrDfsGetInfo](#) methods when used to enumerate DFS links and DFS targets in a namespace or to get information about a DFS link. The structure contains information about the target of a DFS root or DFS link.

The **DFS\_STORAGE\_INFO** structure has the following format.

```
typedef struct _DFS_STORAGE_INFO {
    unsigned long State;
    [string] WCHAR* ServerName;
    [string] WCHAR* ShareName;
} DFS_STORAGE_INFO;
```

**State:** Refers to the **State** field of [DFS\\_INFO\\_106](#). For more information, see section [2.2.4.6](#).

**ServerName:** The pointer to a null-terminated Unicode string containing the DFS target host name.

**ShareName:** The pointer to a null-terminated Unicode string containing the DFS target share name.

[DFS\\_INFO\\_3](#) and [DFS\\_INFO\\_4](#) structures contain one or more **DFS\_STORAGE\_INFO** structures, one for each DFS target.

### 2.2.2.6 DFS\_STORAGE\_INFO\_1

The **DFS\_STORAGE\_INFO\_1** structure relates to the [NetrDfsEnum](#), [NetrDfsEnumEx](#), and [NetrDfsGetInfo](#) methods when used to enumerate DFS links and targets in a namespace or to get information about a DFS link. The structure contains data about a DFS target, including the host name and share name, as well as the target state and priority. For more information on prioritization, see section [2.2.2.7](#).

The **DFS\_STORAGE\_INFO\_1** structure has the following format.

```
typedef struct _DFS_STORAGE_INFO_1 {
    unsigned long State;
    [string] WCHAR* ServerName;
    [string] WCHAR* ShareName;
    DFS_TARGET_PRIORITY TargetPriority;
} DFS_STORAGE_INFO_1,
*PDFS_STORAGE_INFO_1,
*LPDFS_STORAGE_INFO_1;
```

**State:** Refers to the State field of [DFS\\_INFO\\_106](#). For more information, see section [2.2.4.6](#).

**ServerName:** A pointer to a null-terminated Unicode string containing the DFS target host name.

**ShareName:** A pointer to a null-terminated Unicode string containing the DFS target share name.

**TargetPriority:** A **DFS\_TARGET\_PRIORITY** structure containing the priority class and priority rank.

### 2.2.2.7 DFS\_TARGET\_PRIORITY

The **DFS\_TARGET\_PRIORITY** structure relates to the [NetrDfsSetInfo](#) and [NetrDfsSetInfo2](#) methods when used to set the priority of a DFS target in referrals from a server. It also relates to the [DFS\\_STORAGE\\_INFO\\_1](#) structure that the [NetrDfsEnum](#), [NetrDfsEnumEx](#), and [NetrDfsGetInfo](#) methods return. The structure defines the priority of a DFS target. The DFS targets can be prioritized independently of **site cost**. The DFS target priority is manually assigned to link targets and root targets and allows for load balancing of clients.

The **DFS\_TARGET\_PRIORITY** structure has the following format.

```
typedef struct _DFS_TARGET_PRIORITY {
    DFS_TARGET_PRIORITY_CLASS TargetPriorityClass;
    unsigned short TargetPriorityRank;
    unsigned short Reserved;
} DFS_TARGET_PRIORITY;
```

**TargetPriorityClass:** The [DFS\\_TARGET\\_PRIORITY\\_CLASS](#) enumeration value that specifies the priority class of the target. For more information, see section [2.2.2.8](#).

**TargetPriorityRank:** The priority rank of the target, ranging in value from 0x0000 to 0x001F, where 0x0000 is the highest rank. Priority ranks apply only within a priority class, not across priority classes.

**Reserved:** MUST be set to 0 by the sender and ignored by the receiver.

### 2.2.2.8 DFS\_TARGET\_PRIORITY\_CLASS

The **DFS\_TARGET\_PRIORITY\_CLASS** enumeration relates to the [NetrDfsSetInfo](#) and [NetrDfsSetInfo2](#) methods when used to set the priority of DFS targets in referrals from a server. For more information on prioritization, see section [2.2.2.7](#). The enumeration defines five possible DFS target priority class settings.

```
typedef [v1_enum] enum _DFS_TARGET_PRIORITY_CLASS
{
    DfsInvalidPriorityClass = -1,
    DfsSiteCostNormalPriorityClass = 0,
    DfsGlobalHighPriorityClass = 1,
    DfsSiteCostHighPriorityClass = 2,
    DfsSiteCostLowPriorityClass = 3,
    DfsGlobalLowPriorityClass = 4
} DFS_TARGET_PRIORITY_CLASS;
```

**DfsInvalidPriorityClass:** This is not a valid priority class.

**DfsSiteCostNormalPriorityClass:** The default or "normal" site cost priority class for a DFS target.

**DfsGlobalHighPriorityClass:** The highest priority class for a DFS target. Targets assigned to this class receive global preference.

**DfsSiteCostHighPriorityClass:** The highest site cost priority class for a DFS target. Targets assigned to this class receive the highest preference among targets of the same site cost for a given DFS client.

**DfsSiteCostLowPriorityClass:** The lowest site cost priority class for a DFS target. Targets assigned to this class receive the least preference among targets of the same site cost for a given DFS client.

**DfsGlobalLowPriorityClass:** The lowest priority class level for a DFS target. Targets assigned to this class receive the least preference globally.

The underlying data type of this enumeration is long integer.

The order of priority classes, from highest to lowest, is as follows:

- DfsGlobalHighPriorityClass
- DfsSiteCostHighPriorityClass
- DfsSiteCostNormalPriorityClass
- DfsSiteCostLowPriorityClass
- DfsGlobalLowPriorityClass

Server targets are initially grouped into global high-priority, normal-priority, and global low-priority classes. The normal-priority class is then subdivided, based on site cost, into site cost high-priority, site cost normal-priority, and site-cost low-priority classes.

For example, all server targets with a site cost value of 0 are grouped into site cost high-priority, normal-priority, and low-priority classes. Then, all server targets with higher site costs are likewise separated into site cost high-priority, normal-priority, and low-priority classes. Thus, a server target with a site cost value of 0 and a site cost low-priority class is still ranked higher than a server target with a site cost value of 1 and a site cost high-priority class.

Be aware that the value for a "normal-priority class" is set to 0 even though it is lower in priority than DfsGlobalHighPriorityClass and DfsSiteCostHighPriorityClass. This is the default priority class setting. For added granularity, priority rank can be used to discriminate within a priority class.

### 2.2.2.9 DFSM\_ROOT\_LIST

The **DFSM\_ROOT\_LIST** structure relates to the [NetrDfsAdd2](#), [NetrDfsAddFtRoot](#), and [NetrDfsSetInfo2](#) methods when used to add a DFS link or a DFS root target, or to modify the configuration of a domain-based DFS namespace. The structure contains an array of [DFSM\\_ROOT\\_LIST\\_ENTRY](#) structures, each of which contains information about a DFS root target.

The **DFSM\_ROOT\_LIST** structure has the following format.

```
typedef struct _DFSM_ROOT_LIST {  
    DWORD cEntries;
```

```
[size_is(cEntries)] DFSM_ROOT_LIST_ENTRY Entry[];  
} DFSM_ROOT_LIST;
```

**cEntries:** The number of DFS targets. The value of this member indicates the size of the array in the Entry member.

**Entry:** An array of **DFSM\_ROOT\_LIST\_ENTRY** structures. Each structure provides information about one DFS target. For more information, see section [2.2.2.10](#).

### 2.2.2.10 DFSM\_ROOT\_LIST\_ENTRY

The **DFSM\_ROOT\_LIST\_ENTRY** structure relates to the [NetrDfsAdd2](#), [NetrDfsAddFtRoot](#), and [NetrDfsSetInfo2](#) methods when used to add a DFS link or a DFS root target, or to modify the configuration of a domain-based DFS namespace. The structure contains information about a DFS root target.

The **DFSM\_ROOT\_LIST\_ENTRY** structure has the following format.

```
typedef struct _DFSM_ROOT_LIST_ENTRY {  
    [string, unique] WCHAR* ServerShare;  
} DFSM_ROOT_LIST_ENTRY;
```

**ServerShare:** Specifies a DFS root target.

### 2.2.2.11 DFS\_NAMESPACE\_VERSION\_ORIGIN

The **DFS\_NAMESPACE\_VERSION\_ORIGIN** is an enumeration that relates to the [NetrDfsGetSupportedNamespaceVersion](#) method when used to determine the supported DFS metadata version number.

The **DFS\_NAMESPACE\_VERSION\_ORIGIN** enumeration has the following format.

```
typedef enum _DFS_NAMESPACE_VERSION_ORIGIN  
{  
    DFS_NAMESPACE_VERSION_ORIGIN_COMBINED = 0,  
    DFS_NAMESPACE_VERSION_ORIGIN_SERVER,  
    DFS_NAMESPACE_VERSION_ORIGIN_DOMAIN  
} DFS_NAMESPACE_VERSION_ORIGIN;
```

**DFS\_NAMESPACE\_VERSION\_ORIGIN\_COMBINED:** This value is not used in communication.

**DFS\_NAMESPACE\_VERSION\_ORIGIN\_SERVER:** The maximum version that a server can support.

**DFS\_NAMESPACE\_VERSION\_ORIGIN\_DOMAIN:** The maximum version that the domain can support.

### 2.2.2.12 DFS\_SUPPORTED\_NAMESPACE\_VERSION\_INFO

The **DFS\_SUPPORTED\_NAMESPACE\_VERSION\_INFO** structure relates to the [NetrDfsGetSupportedNamespaceVersion](#) method when used to determine the domain-based or standalone-based DFS major and minor version information.

The **DFS\_SUPPORTED\_NAMESPACE\_VERSION\_INFO** structure has the following format.

```
typedef struct _DFS_SUPPORTED_NAMESPACE_VERSION_INFO {
    unsigned long DomainDfsMajorVersion;
    unsigned long DomainDfsMinorVersion;
    ULONGLONG DomainDfsCapabilities;
    unsigned long StandaloneDfsMajorVersion;
    unsigned long StandaloneDfsMinorVersion;
    ULONGLONG StandaloneDfsCapabilities;
} DFS_SUPPORTED_NAMESPACE_VERSION_INFO,
*PDFS_SUPPORTED_NAMESPACE_VERSION_INFO;
```

**DomainDfsMajorVersion:** A value containing the major version number of the DFS metadata format supported by a domain-based DFS namespace.

**DomainDfsMinorVersion:** A value containing the minor version number of the DFS metadata format supported by a domain-based DFS namespace.

**DomainDfsCapabilities:** A value containing the capability information of a domain-based DFS namespace.

**StandaloneDfsMajorVersion:** A value containing the major version number of a stand-alone DFS namespace.

**StandaloneDfsMinorVersion:** A value containing the minor version number of a stand-alone DFS namespace.

**StandaloneDfsCapabilities:** A value containing the capability information of a stand-alone DFS namespace.

**DomainDfsCapabilities** and **StandaloneDfsCapabilities** are bit fields with the following defined value.

Value	Meaning
DFS_NAMESPACE_CAPABILITY_ABDE 0x0000000000000001	This specifies support for Access Based Directory Enumeration (ABDE) mode. <a href="#">&lt;4&gt;</a>

When this structure is used for communication, all undefined bit fields MUST be set to zero. A client SHOULD ignore all bit fields it does not understand.

### 2.2.2.13 DFS Volume State

The following table lists the valid states for a DFS root or a DFS link, and it relates to the **State** field of the **DFS\_INFO\_2**, **DFS\_INFO\_4**, **DFS\_INFO\_5**, **DFS\_INFO\_6**, and **DFS\_INFO\_8** structures. The bitmask **DFS\_VOLUME\_STATES** (0x0000000F) MUST be used to extract the state of a DFS root or a DFS link from the **State** field.

Value	Meaning
DFS_VOLUME_STATE_OK 0x00000001	The DFS root or DFS link is initialized to this state. In this state the DFS root or link is available for referral request. This state is persisted to the DFS metadata.
RESERVED 0x00000002	This value is reserved and MUST NOT be used.
DFS_VOLUME_STATE_OFFLINE 0x00000003	The DFS link is offline, and none of the DFS targets will be included in referral response. This flag is valid only for a DFS link and cannot be set on a DFS root. This state is persisted to the DFS metadata.
DFS_VOLUME_STATE_ONLINE 0x00000004	The DFS link is online and available for referral request. This flag is valid only for a DFS link and cannot be set on a DFS root. This state is persisted to the DFS metadata.

### 2.2.3 Get Info Data Types

The structures in this section relate to the [NetrDfsGetInfo](#), [NetrDfsEnum](#), and [NetrDfsEnumEx](#) methods when used to retrieve information about the DFS server configuration. The usage model of these structures is for the client to specify a *Level* parameter to indicate which case of the [DFS\\_INFO\\_STRUCT](#) to use.

#### 2.2.3.1 DFS\_INFO\_1

The **DFS\_INFO\_1** structure contains the name of a DFS root or DFS link.

The **DFS\_INFO\_1** structure has the following format.

```
typedef struct _DFS_INFO_1 {
    [string] WCHAR* EntryPath;
} DFS_INFO_1;
```

**EntryPath:** The pointer to a DFS root or a DFS link path.

#### 2.2.3.2 DFS\_INFO\_2

The **DFS\_INFO\_2** structure contains information for a DFS root or DFS link.

The **DFS\_INFO\_2** structure has the following format.

```
typedef struct _DFS_INFO_2 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    DWORD NumberOfStorages;
} DFS_INFO_2;
```

**EntryPath:** A pointer to a DFS root or a DFS link path.

**Comment:** A pointer to a null-terminated Unicode string containing a comment that is used for informational purposes and is associated with the DFS root or DFS link. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** This field has the state of the DFS root or DFS link. For a DFS root, this field also specifies whether the DFS namespace is stand-alone or domain-based.

The DFS\_VOLUME\_STATES bitmask (0x0000000F) MUST be used to extract the following DFS root or DFS link state from this field. For more information about some of these states, see section [2.2.2.13](#).

Value	Meaning
DFS_VOLUME_STATE_OK 0x00000001	The specified DFS root or DFS link is in the normal state.
RESERVED 0x00000002	This value is reserved and MUST NOT be used.
DFS_VOLUME_STATE_OFFLINE 0x00000003	The DFS link is offline, and none of the DFS targets will be included in the referral response. This flag is valid only for a DFS link and cannot be set on a DFS root. This state is persisted to the DFS metadata.
DFS_VOLUME_STATE_ONLINE 0x00000004	The DFS link is online and available for referral request. This flag is valid only for a DFS link and cannot be set on a DFS root. This state is persisted to the DFS metadata.

The DFS\_VOLUME\_FLAVORS bitmask (0x00000300) MUST be used to extract the following DFS namespace flavor from this field.

Value	Meaning
DFS_VOLUME_FLAVOR_STANDALONE 0x00000100	Stand-alone DFS namespace.
DFS_VOLUME_FLAVOR_AD_BLOB 0x00000200	domainv1-based or <b>domainv2-based DFS namespace</b> .

**NumberOfStorages:** Number of DFS targets for the root or link.

### 2.2.3.3 DFS\_INFO\_3

The **DFS\_INFO\_3** structure contains information for a DFS root or a DFS link.

The **DFS\_INFO\_3** structure has the following format.

```
typedef struct _DFS_INFO_3 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    DWORD NumberOfStorages;
    [size_is(NumberOfStorages)] DFS_STORAGE_INFO* Storage;
} DFS_INFO_3;
```

**EntryPath:** Pointer to a DFS root or DFS link path.

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** Refers to the State field of [DFS\\_INFO\\_2](#). For more information, see section [2.2.3.2](#).

**NumberOfStorages:** The number of DFS targets for this root or link.

**Storage:** A pointer to an array of [DFS\\_STORAGE\\_INFO](#) structures containing information about each target. (For more information, see section [2.2.2.5](#)). The NumberOfStorages member specifies the number of structures within this storage array.

#### 2.2.3.4 DFS\_INFO\_4

The **DFS\_INFO\_4** structure contains information for a DFS root or a DFS link.

The **DFS\_INFO\_4** structure has the following format.

```
typedef struct _DFS_INFO_4 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    GUID Guid;
    DWORD NumberOfStorages;
    [size_is(NumberOfStorages)] DFS_STORAGE_INFO* Storage;
} DFS_INFO_4;
```

**EntryPath:** A pointer to a DFS root or a DFS link path.

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** Refers to the State field of [DFS\\_INFO\\_2](#). For more information, see section [2.2.3.2](#).

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**Guid:** The GUID of this root or link.

**NumberOfStorages:** The number of DFS targets for this root or link. There are no protocol-specified restrictions on the number of targets for a root or link.

**Storage:** A pointer to an array of [DFS\\_STORAGE\\_INFO](#) structures containing information about each target. (For more information, see section [2.2.2.5](#)). The NumberOfStorages member specifies the number of structures within this storage array.

### 2.2.3.5 DFS\_INFO\_5

The **DFS\_INFO\_5** structure contains information for a DFS root or a DFS link.

The **DFS\_INFO\_5** structure has the following format.

```
typedef struct _DFS_INFO_5 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    GUID Guid;
    unsigned long PropertyFlags;
    unsigned long MetadataSize;
    DWORD NumberOfStorages;
} DFS_INFO_5;
```

**EntryPath:** A pointer to a DFS root or a DFS link path.

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** Refers to the State field of [DFS\\_INFO\\_2](#). For more information, see section [2.2.3.2](#).

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**Guid:** The GUID of this root or link.

**PropertyFlags:** A bit field in which each bit is responsible for a specific property applicable to the entire DFS namespace, the DFS root, or an individual DFS link, depending on the actual property. Any combination of bits is allowed, unless indicated otherwise. The following are valid bit definitions for this field.

Value	Meaning
DFS_PROPERTY_FLAG_INSITE_REFERRALS 0x00000001	When set, indicates that <b>DFS in-site referral mode</b> is enabled.
DFS_PROPERTY_FLAG_ROOT_SCALABILITY 0x00000002	When set, indicates DFS root scalability mode is enabled. This flag is valid only for the DFS root of a domain-based DFS namespace.
DFS_PROPERTY_FLAG_SITE_COSTING 0x00000004	When set, indicates <b>DFS referral site costing</b> is enabled. This flag is valid only for a DFS root.
DFS_PROPERTY_FLAG_TARGET_FAILBACK 0x00000008	When set, indicates <b>DFS client target failback</b> is enabled.
DFS_PROPERTY_FLAG_CLUSTER_ENABLED 0x00000010	When set, indicates <b>clustered DFS namespace</b> is enabled.
DFS_PROPERTY_FLAG_ABDE 0x00000020	When set, enables <b>Access Based Directory Enumeration (ABDE) mode</b> on a domainv2-based

Value	Meaning
	DFS namespace or a stand-alone DFS namespace. <5>This flag is not supported on domainv1-based namespaces.

**MetadataSize:** The size, in bytes, of the DFS metadata of the DFS namespace. For a DFS link, this MUST be 0.

**NumberOfStorages:** The number of DFS targets for this root or link.

### 2.2.3.6 DFS\_INFO\_6

The **DFS\_INFO\_6** structure contains information for a DFS root or a DFS link.

The **DFS\_INFO\_6** structure has the following format.

```
typedef struct _DFS_INFO_6 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    GUID Guid;
    unsigned long PropertyFlags;
    unsigned long MetadataSize;
    DWORD NumberOfStorages;
    [size_is(NumberOfStorages)] DFS_STORAGE_INFO_1* Storage;
} DFS_INFO_6;
```

**EntryPath:** A pointer to a DFS root or a DFS link path.

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** Refers to the State field of [DFS\\_INFO\\_2](#). For more information, see section [2.2.3.2](#).

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**Guid:** The GUID of this root or link.

**PropertyFlags:** Refers to the PropertyFlags field of [DFS\\_INFO\\_5](#). For more information, see section [2.2.3.5](#).

**MetadataSize:** The size of the DFS metadata of the DFS namespace. This MUST be 0 for a DFS link.

**NumberOfStorages:** The number of DFS targets for this root or link. The protocol imposes no restrictions on the number of roots or links.

**Storage:** A pointer to an array of [DFS\\_STORAGE\\_INFO\\_1](#) structures containing information about each target. The NumberOfStorages member specifies the number of structures within this storage array.

### 2.2.3.7 DFS\_INFO\_7

The **DFS\_INFO\_7** structure contains information about a DFS root.

The **DFS\_INFO\_7** structure has the following format.

```
typedef struct _DFS_INFO_7 {
    GUID GenerationGuid;
} DFS_INFO_7;
```

**GenerationGuid:** This GUID is modified each time DFS metadata is updated.

This data type is used to detect when the metadata of a DFS namespace has changed. It MUST be supported for domain-based DFS namespaces. It MAY be supported for stand-alone DFS namespaces; a null GUID (all 128-bits are 0) MUST be returned if this is not supported. [<6>](#)

### 2.2.3.8 DFS\_INFO\_8

The **DFS\_INFO\_8** structure contains information for a DFS root or a DFS link.

The **DFS\_INFO\_8** structure has the following format.

```
typedef struct _DFS_INFO_8 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    GUID Guid;
    unsigned long PropertyFlags;
    unsigned long MetadataSize;
    ULONG SecurityDescriptorLength;
    [size_is(SecurityDescriptorLength)]
    PCHAR pSecurityDescriptor;
    DWORD NumberOfStorages;
} DFS_INFO_8,
*LPDFS_INFO_8;
```

**EntryPath:** A pointer to a DFS root or a DFS link path.

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** Refers to the State field of [DFS\\_INFO\\_2](#). For more information, see section [2.2.3.2](#).

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**Guid:** The GUID of this root or link.

**PropertyFlags:** Refers to the PropertyFlags field of [DFS\\_INFO\\_5](#). For more information, see section [2.2.3.5](#).

**MetadataSize:** The size, in bytes, of the DFS metadata of the DFS namespace. For a DFS link, this MUST be 0.

**SecurityDescriptorLength:** The length, in bytes, of the buffer that the **pSecurityDescriptor** field points to.

**pSecurityDescriptor:** A self-relative security descriptor to be associated with a DFS link. For more information on security descriptors, see [\[MS-DTYP\]](#) section 2.4.6.

**NumberOfStorages:** The number of DFS targets for this root or link. The protocol imposes no restrictions on the number of roots or links.

### 2.2.3.9 DFS\_INFO\_9

The **DFS\_INFO\_9** structure contains information for a DFS root or a DFS link.

The **DFS\_INFO\_9** structure has the following format.

```
typedef struct _DFS_INFO_9 {
    [string] WCHAR* EntryPath;
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    GUID Guid;
    unsigned long PropertyFlags;
    unsigned long MetadataSize;
    ULONG SecurityDescriptorLength;
    [size_is(SecurityDescriptorLength)]
    PCHAR pSecurityDescriptor;
    DWORD NumberOfStorages;
    [size_is(NumberOfStorages)] LPDFS_STORAGE_INFO_1 Storage;
} DFS_INFO_9,
*LPDFS_INFO_9;
```

**EntryPath:** A pointer to a DFS root or a DFS link path.

**Comment:** Pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. There are no protocol-specified restrictions on the length or content of this string. The comment is meant for human readability and has no effect on server functionality.

**State:** Refers to the State field of [DFS\\_INFO\\_2](#). For more information, see section [2.2.3.2](#).

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**Guid:** The GUID of this root or link.

**PropertyFlags:** Refers to the PropertyFlags field of [DFS\\_INFO\\_5](#). For more information, see section [2.2.3.5](#).

**MetadataSize:** The size, in bytes, of the DFS metadata of the DFS namespace. For a DFS link, this MUST be 0.

**SecurityDescriptorLength:** The length, in bytes, of the buffer that the **pSecurityDescriptor** field points to.

**pSecurityDescriptor:** A self-relative security descriptor to be associated with a DFS link. For more information on security descriptors, see [\[MS-DTYP\]](#) section 2.4.6.

**NumberOfStorages:** The number of DFS targets for this root or link. The protocol imposes no restrictions on the number of roots or links.

**Storage:** A pointer to an array of [DFS\\_STORAGE\\_INFO\\_1](#) structures containing information about each target. The NumberOfStorages member specifies the number of structures within this storage array.

For information on target priority rank and class information, see section [2.2.2.6](#).

### 2.2.3.10 DFS\_INFO\_50

The **DFS\_INFO\_50** structure is used to get the DFS metadata version and the capability information of an existing DFS namespace.

The **DFS\_INFO\_50** structure has the following format.

```
typedef struct _DFS_INFO_50 {
    unsigned long NamespaceMajorVersion;
    unsigned long NamespaceMinorVersion;
    unsigned __int64 NamespaceCapabilities;
} DFS_INFO_50;
```

**NamespaceMajorVersion:** A value containing the major version number used to determine the DFS metadata format supported in a domain-based DFS namespace or a stand-alone DFS namespace. [<7>](#)

**NamespaceMinorVersion:** A value containing the minor version number used to determine the DFS metadata format supported in a domain-based DFS namespace or stand-alone DFS namespace. [<8>](#)

**NamespaceCapabilities:** A value containing the capability information of a DFS namespace.

Value	Meaning
DFS__NAMESPACE_CAPABILITY_ABDE 0x0000000000000001	The specified DFS root supports using Access Based Directory Enumeration (ABDE) mode. <a href="#">&lt;9&gt;</a>

### 2.2.4 Set Info Data Types

The structures in this section relate to the [NetrDfsSetInfo](#) and [NetrDfsSetInfo2](#) methods when used to retrieve or set the configuration of the DFS server. The usage model of these structures is for the client to specify a *Level* parameter to indicate which [DFS\\_INFO\\_STRUCT](#) case to use.

#### 2.2.4.1 DFS\_INFO\_101

The **DFS\_INFO\_101** structure describes the storage state on a root, link, root target, or link target.

The **DFS\_INFO\_101** structure has the following format.

```
typedef struct _DFS_INFO_101 {
    unsigned long State;
```

```
} DFS_INFO_101;
```

**State:** The state of the root, link, root target, or link target.

The following table lists the valid states that can be set for a root or a link. Some of these states are used to perform a server operation and are not persisted to the DFS metadata, as specified below. For more information about some of these states, see section [2.2.2.13](#).

Value	Meaning
DFS_VOLUME_STATE_OK 0x00000001	The specified DFS root or DFS link is in the normal state.
DFS_VOLUME_STATE_OFFLINE 0x00000003	The specified DFS link is offline or unavailable. This flag is valid only for a DFS link. This state is persisted to the DFS metadata.
DFS_VOLUME_STATE_ONLINE 0x00000004	The specified DFS link is available. This flag is valid only for a DFS link. This state is persisted to the DFS metadata.
DFS_VOLUME_STATE_RESYNCHRONIZE 0x00000010	Forces a resynchronization on the DFS root. This flag is valid only for a DFS root. This operation is an incremental synchronization that picks up only changed objects in the metadata. This state is used to perform a server operation. It is not persisted to the DFS metadata.
DFS_VOLUME_STATE_STANDBY 0x00000020	Sets a root volume to standby mode. This flag is valid only for a clustered DFS root. This state is used to perform a server operation. It is not persisted to the DFS metadata.
DFS_VOLUME_STATE_FORCE_SYNC 0x00000040	Forces a full resynchronization operation on the DFS root target of a specified domainv2-based DFS namespace or stand-alone DFS namespace to identify DFS links that have been added or deleted. This is not supported on a domainv1-based DFS namespace. DFS links MUST NOT be specified. This state is used to perform a server operation. It is not persisted to the DFS metadata.

DFS\_VOLUME\_STATES (0x0000000F) is not relevant here, because it is a mask used when reading the volume state, not for setting it.

The following table lists the valid states that can be set for a root target or a link target.

Value	Meaning
DFS_STORAGE_STATE_OFFLINE 0x00000001	This target is offline and unavailable for use.
DFS_STORAGE_STATE_ONLINE 0x00000002	This target is online and available for use.

### 2.2.4.2 DFS\_INFO\_102

The **DFS\_INFO\_102** structure contains a time-out value for a DFS root or a DFS link.

The **DFS\_INFO\_102** structure has the following format.

```
typedef struct _DFS_INFO_102 {
    unsigned long Timeout;
} DFS_INFO_102;
```

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

### 2.2.4.3 DFS\_INFO\_103

The **DFS\_INFO\_103** structure contains properties that set specific behaviors for a DFS root or a DFS link.

The **DFS\_INFO\_103** structure has the following format.

```
typedef struct _DFS_INFO_103 {
    unsigned long PropertyFlagMask;
    unsigned long PropertyFlags;
} DFS_INFO_103;
```

**PropertyFlagMask:** Indicates which bits in the **PropertyFlags** field are considered for modification of DFS namespace root or link properties.

Value	Meaning
DFS_PROPERTY_FLAG_INSITE_REFERRALS 0x00000001	Valid for domain and stand-alone DFS roots and links.
DFS_PROPERTY_FLAG_ROOT_SCALABILITY 0x00000002	This flag is valid only for the DFS root of a domain-based DFS namespace.
DFS_PROPERTY_FLAG_SITE_COSTING 0x00000004	This flag is valid only for a DFS root.
DFS_PROPERTY_FLAG_TARGET_FAILBACK 0x00000008	Valid for domain and stand-alone DFS roots and links.
DFS_PROPERTY_FLAG_ABDE 0x00000020	Valid only for a domainv2-based DFS namespace or stand-alone DFS namespace root. <10> This flag is not supported on domainv1-based namespaces.

**PropertyFlags:** A bit field in which each bit is responsible for a specific property applicable to the whole DFS namespace, the DFS root, or an individual DFS link, depending on the actual property. Any combination of bits is allowed, unless indicated otherwise. The server considers the bits in this field only when the corresponding bit in the **PropertyFlagMask** field is set. The following table lists the valid bits for this field and describes the actions taken when each bit is set or not set in the request.

Value	Meaning
DFS_PROPERTY_FLAG_INSITE_REFERRALS 0x00000001	When set, enables DFS in-site referral mode. When not set, disables DFS in-site referral mode.
DFS_PROPERTY_FLAG_ROOT_SCALABILITY 0x00000002	When set, enables DFS root scalability mode. When not set, disables DFS root scalability mode.
DFS_PROPERTY_FLAG_SITE_COSTING 0x00000004	When set, enables DFS referral site costing. When not set, disables DFS referral site costing.
DFS_PROPERTY_FLAG_TARGET_FAILBACK 0x00000008	When set, enables DFS client target failback. When not set, disables DFS client target failback.
DFS_PROPERTY_FLAG_ABDE 0x00000020	When set, enables ABDE mode on a domainv2-based DFS namespace or stand-alone DFS namespace. When not set, disables ABDE mode on a domainv2-based DFS namespace or stand-alone DFS namespace.

#### 2.2.4.4 DFS\_INFO\_104

The **DFS\_INFO\_104** structure contains the priority of a DFS root target or a DFS link target.

The **DFS\_INFO\_104** structure has the following format.

```
typedef struct _DFS_INFO_104 {
    DFS_TARGET_PRIORITY TargetPriority;
} DFS_INFO_104;
```

**TargetPriority:** A [DFS\\_TARGET\\_PRIORITY](#) structure that indicates the priority rank and priority class of a target. For more information on prioritization, see section [2.2.2.7](#).

#### 2.2.4.5 DFS\_INFO\_105

The **DFS\_INFO\_105** structure contains information about a DFS root or DFS link, including comment, state, time-out, and DFS behaviors specified by property flags.

The **DFS\_INFO\_105** structure has the following format.

```
typedef struct _DFS_INFO_105 {
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    unsigned long PropertyFlagMask;
    unsigned long PropertyFlags;
} DFS_INFO_105;
```

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality.

**State:** The following table lists the valid states that can be set for links. All other values are reserved and MUST NOT be used. For more information about some of these states, see section [2.2.2.13](#).

Value	Meaning
0x00000000	Indicates that the existing state MUST NOT be changed.
DFS_VOLUME_STATE_OFFLINE 0x00000003	The specified DFS link is offline or unavailable. This flag is valid only for a DFS link.
DFS_VOLUME_STATE_ONLINE 0x00000004	The specified DFS link is available. This flag is valid only for a DFS link.

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**PropertyFlagMask:** Indicates which bits in the **PropertyFlags** field are valid.

**PropertyFlags:** Refers to the **PropertyFlags** field of [DFS\\_INFO\\_103](#), as specified in section [2.2.4.3](#).

#### 2.2.4.6 DFS\_INFO\_106

The **DFS\_INFO\_106** structure contains the storage state and priority of a DFS root target or a DFS link target. For more information on prioritization, see section [2.2.2.7](#).

The **DFS\_INFO\_106** structure has the following format.

```
typedef struct _DFS_INFO_106 {
    DWORD State;
    DFS_TARGET_PRIORITY TargetPriority;
} DFS_INFO_106;
```

**State:** The state of the target. Contains one of the following valid state values.

Value	Meaning
DFS_STORAGE_STATE_OFFLINE 0x00000001	This target is offline and unavailable for use.
DFS_STORAGE_STATE_ONLINE 0x00000002	This target is online and available for use.

**TargetPriority:** A **DFS\_TARGET\_PRIORITY** structure that indicates the priority class and rank of the DFS target.

#### 2.2.4.7 DFS\_INFO\_107

The **DFS\_INFO\_107** structure contains information about a DFS root or DFS link, including comment, state, time-out, security descriptor, and DFS behaviors specified by property flags.

The **DFS\_INFO\_107** structure has the following format.

```

typedef struct _DFS_INFO_107 {
    [string] WCHAR* Comment;
    DWORD State;
    unsigned long Timeout;
    unsigned long PropertyFlagMask;
    unsigned long PropertyFlags;
    ULONG SecurityDescriptorLength;
    [size_is(SecurityDescriptorLength)]
    PCHAR pSecurityDescriptor;
} DFS_INFO_107;

```

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human readability and does not affect server functionality.

**State:** The states that can be set for links. The following table lists such states. All other values are reserved and MUST NOT be used. For more information about some of these states, see section [2.2.2.13](#).

Value	Meaning
0x00000000	Indicates that the existing state MUST NOT be changed.
DFS_VOLUME_STATE_OFFLINE 0x00000003	The specified DFS link is offline or unavailable. This flag is valid only for a DFS link.
DFS_VOLUME_STATE_ONLINE 0x00000004	The specified DFS link is available. This flag is valid only for a DFS link.

**Timeout:** The time-out, in seconds, associated with the root or link and used in a DFS referral response to a DFS client.

**PropertyFlagMask:** Indicates which bits in the **PropertyFlags** field are valid.

**PropertyFlags:** Refers to the **PropertyFlags** field of [DFS INFO 103](#), as specified in section [2.2.4.3](#).

**SecurityDescriptorLength:** The length, in bytes, of the buffer that the **pSecurityDescriptor** field points to.

**pSecurityDescriptor:** A self-relative security descriptor to be associated with a DFS link. For more information on security descriptors, see [\[MS-DTYP\]](#) section 2.4.6.

## 2.2.5 Special Info Data Types

The structures in this section relate to the [NetrDfsEnum](#), [NetrDfsEnumEx](#), [NetrDfsGetInfo](#), [NetrDfsSetInfo](#), and [NetrDfsSetInfo2](#) methods when used to retrieve or set the DFS server configuration. The usage model of these structures is for the client to specify a *Level* parameter to indicate which case of the [DFS INFO STRUCT](#) to use.

### 2.2.5.1 DFS\_INFO\_100

The **DFS\_INFO\_100** structure relates to the [NetrDfsGetInfo](#), [NetrDfsSetInfo](#), and [NetrDfsSetInfo2](#) methods when used to retrieve or set comment text about a DFS root or a DFS link. The structure contains a comment associated with a DFS root or a DFS link.

The **DFS\_INFO\_100** structure has the following format.

```
typedef struct _DFS_INFO_100 {
    [string] WCHAR* Comment;
} DFS_INFO_100;
```

**Comment:** A pointer to a null-terminated Unicode string containing a comment associated with the DFS root or DFS link that is for informational purposes. This string has no protocol-specified restrictions on length or content. The comment is meant for human readability and does not affect server functionality.

### 2.2.5.2 DFS\_INFO\_150

The **DFS\_INFO\_150** structure relates to the [NetrDfsGetInfo](#), [NetrDfsSetInfo](#), and [NetrDfsSetInfo2](#) methods when used to retrieve or set security descriptors associated with a DFS link. The structure contains the self-relative security descriptor associated with a DFS link.

The **DFS\_INFO\_150** structure has the following format.

```
typedef struct _DFS_INFO_150 {
    ULONG SecurityDescriptorLength;
    [size_is(SecurityDescriptorLength)]
    PCHAR pSecurityDescriptor;
} DFS_INFO_150;
```

**SecurityDescriptorLength:** The length, in bytes, of the buffer that the **pSecurityDescriptor** field points to.

**pSecurityDescriptor:** A self-relative security descriptor associated with DFS. For more information on security descriptors, see [\[MS-DTYP\]](#) section 2.4.6.

### 2.2.5.3 DFS\_INFO\_200

The **DFS\_INFO\_200** structure relates to the [NetrDfsEnumEx](#) method when used to enumerate all of the domain-based DFS namespace in a domain. The structure contains the name of a domain-based DFS namespace. The **DFS\_INFO\_200** structure has the following format.

```
typedef struct _DFS_INFO_200 {
    [string] WCHAR* FtDfsName;
} DFS_INFO_200;
```

**FtDfsName:** A pointer to a DFS root path.

## 2.2.5.4 DFS\_INFO\_300

The **DFS\_INFO\_300** structure relates to the [NetrDfsEnum](#) and [NetrDfsEnumEx](#) methods when used to enumerate DFS roots hosted on a server. The structure contains the name and type (domain-based or stand-alone) of a DFS namespace. The **DFS\_INFO\_300** structure has the following format.

```
typedef struct _DFS_INFO_300 {
    DWORD Flags;
    [string] WCHAR* DfsName;
} DFS_INFO_300;
```

**Flags:** This value specifies the type of the DFS namespace. This MUST have one of the following two permitted values.

Value	Meaning
DFS_VOLUME_FLAVOR_STANDALONE 0x00000100	Stand-alone DFS namespace.
DFS_VOLUME_FLAVOR_AD_BLOB 0x00000200	Domain-based DFS namespace.

**DfsName:** A pointer to a DFS root path.

## 2.2.6 Enum Info Data Types

The structures in this section relate to the [NetrDfsEnum](#) and [NetrDfsEnumEx](#) methods when used to enumerate and retrieve the configuration of the DFS server. The usage model of these structures is for the client to specify a *Level* parameter to indicate which case of the [DFS\\_INFO\\_ENUM\\_STRUCT](#) to use.

### 2.2.6.1 DFS\_INFO\_1\_CONTAINER

The **DFS\_INFO\_1\_CONTAINER** structure contains an array of [DFS\\_INFO\\_1](#) structures. The **DFS\_INFO\_1\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_1_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_1* Buffer;
} DFS_INFO_1_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_1** structures.

### 2.2.6.2 DFS\_INFO\_2\_CONTAINER

The **DFS\_INFO\_2\_CONTAINER** structure contains an array of [DFS\\_INFO\\_2](#) structures. The **DFS\_INFO\_2\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_2_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_2* Buffer;
} DFS_INFO_2_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_2** structures.

### 2.2.6.3 DFS\_INFO\_3\_CONTAINER

The **DFS\_INFO\_3\_CONTAINER** structure contains an array of [DFS\\_INFO\\_3](#) structures. The **DFS\_INFO\_3\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_3_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_3* Buffer;
} DFS_INFO_3_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_3** structures.

### 2.2.6.4 DFS\_INFO\_4\_CONTAINER

The **DFS\_INFO\_4\_CONTAINER** structure contains an array of [DFS\\_INFO\\_4](#) structures. The **DFS\_INFO\_4\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_4_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_4* Buffer;
} DFS_INFO_4_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_4** structures.

### 2.2.6.5 DFS\_INFO\_5\_CONTAINER

The **DFS\_INFO\_5\_CONTAINER** structure contains an array of [DFS\\_INFO\\_5](#) structures. The **DFS\_INFO\_5\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_5_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_5* Buffer;
} DFS_INFO_5_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_5** structures.

#### 2.2.6.6 DFS\_INFO\_6\_CONTAINER

The **DFS\_INFO\_6\_CONTAINER** structure contains an array of [DFS\\_INFO\\_6](#) structures. The **DFS\_INFO\_6\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_6_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_6* Buffer;
} DFS_INFO_6_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_6** structures.

#### 2.2.6.7 DFS\_INFO\_8\_CONTAINER

The **DFS\_INFO\_8\_CONTAINER** structure contains an array of [DFS\\_INFO\\_8](#) structures. The **DFS\_INFO\_8\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_8_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] LPDFS_INFO_8 Buffer;
} DFS_INFO_8_CONTAINER,
*LPDFS_INFO_8_CONTAINER;
```

**EntriesRead:** The number of **DFS\_INFO\_8** elements in the array.

**Buffer:** The array of **DFS\_INFO\_8** structures.

#### 2.2.6.8 DFS\_INFO\_9\_CONTAINER

The **DFS\_INFO\_9\_CONTAINER** structure contains an array of [DFS\\_INFO\\_9](#) structures. The **DFS\_INFO\_9\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_9_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] LPDFS_INFO_9 Buffer;
} DFS_INFO_9_CONTAINER,
*LPDFS_INFO_9_CONTAINER;
```

**EntriesRead:** The number of **DFS\_INFO\_9** elements in the array.

**Buffer:** The array of **DFS\_INFO\_9** structures.

#### 2.2.6.9 DFS\_INFO\_200\_CONTAINER

The **DFS\_INFO\_200\_CONTAINER** structure contains an array of [DFS\\_INFO\\_200](#) structures. The **DFS\_INFO\_200\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_200_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_200* Buffer;
} DFS_INFO_200_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_200** structures.

### 2.2.6.10 DFS\_INFO\_300\_CONTAINER

The **DFS\_INFO\_300\_CONTAINER** structure contains an array of [DFS INFO 300](#) structures. The **DFS\_INFO\_300\_CONTAINER** structure has the following format.

```
typedef struct _DFS_INFO_300_CONTAINER {
    DWORD EntriesRead;
    [size_is(EntriesRead)] DFS_INFO_300* Buffer;
} DFS_INFO_300_CONTAINER;
```

**EntriesRead:** The number of elements in the array.

**Buffer:** The array of **DFS\_INFO\_300** structures.

## 2.3 Directory Service Schema Elements

The protocol accesses the following **Directory Service (DS)** schema classes and attributes listed in the following table.

For the syntactic specifications of the following <Class> or <Class><Attribute> pairs, or rootDSE attributes, refer either to **Active Directory Domain Services (AD DS)** ([\[MS-ADA2\]](#), [\[MS-ADA3\]](#), and [\[MS-ADSC\]](#)) or to Active Directory Technical Specification ([\[MS-ADTS\]](#)).

Class	Attribute
attributeSchema	rangeUpper
dfsConfiguration	All
ftDFS	objectClass pKT pKTGuid remoteServerName
msDFS-DeletedLinkv2	All objectClass
msDFS-Linkv2	All objectClass
msDFS-NamespaceAnchor	All
msDFS-Namepacev2	All

Class	Attribute
	objectClass
rootDSE	domainFunctionality

This section contains specifications for the [DFS configuration container](#), [DFS namespace object](#), and [pKT attribute](#).

### 2.3.1 DFS Configuration Container

The DFS configuration container is a well-known container in the domain directory that is used to hold the DFS metadata for a domain-based DFS namespace. The container has the following **distinguished name (DN)**.

```
CN=Dfs-Configuration,CN=System,<domain>
```

where <domain> is the DN of the domain.

For example, the DFS configuration container for the contoso.com domain would be named as follows.

```
CN=Dfs-Configuration,CN=System,DC=contoso,DC=com
```

The object class of this object is dfsConfiguration, and its schema is as specified in [\[MS-ADSC\]](#).

### 2.3.2 LDAP Entries for Domain-Based DFS Namespaces

LDAP entries exist in both domainv1-based DFS namespace and domainv2-based DFS namespace. This relationship is shown in the following figure.

**Figure 1: Organization of DFS-related LDAP entries in DFS namespaces**

Each domainv1-based DFS namespace has its DFS metadata stored in the directory service as a BLOB in the **pKT** attribute of an LDAP entry.

Each domainv2-based DFS namespace has one DFS namespace anchor LDAP entry, one DFS namespace LDAP entry below it, and one LDAP entry per DFS link in the namespace under the DFS namespace LDAP entry.

Like the **relative distinguished name (RDN)** of a domainv1-based DFS namespace, the relative distinguished name (RDN) of a domainv2-based DFS namespace entry is based on the DFS namespace. Thus, there is no issue of a name collision with a domainv1-based DFS namespace and a domainv2-based DFS namespace having the same name. The directory service will fail an attempt to create such a scenario.

The following sections specify both domain-based DFS namespace formats.

### 2.3.3 DFS Namespace Object for Domainv1-Based DFS Namespace

An object exists for each domainv1-based DFS namespace in the DFS configuration container. The following is a DN of the object of a domain-based DFS namespace.

```
CN=<DFSNamespaceName>,CN=Dfs-Configuration,CN=System,<domain>
```

where:

- <DFSNamespaceName> is the domain-based DFS namespace.
- <domain> is the DN of the domain.

The following attributes apply to this object.

Attribute	Description
name	The DFS namespace name.
remoteServerName	A multivalued attribute that contains the DFS root targets for the DFS namespace with the value "*" as the last attribute.
pKTGuid	A GUID used as a generation number to detect changes to the DFS metadata. This MUST be updated whenever the <b>pKT</b> attribute is changed.
pKT	The BLOB containing the DFS metadata.

The objectClass of this object is fTDfs, and its schema is specified in [\[MS-ADSC\]](#). The schema of the attributes name, remoteServerName, pKTGuid, and pKT are specified in [\[MS-ADA3\]](#).

#### 2.3.3.1 pKT Attribute Contents (Metadata for Domainv1-Based Namespace)

The **pKT** attribute contains the DFS metadata of the domain-based DFS namespace that the object represents.

The DFS metadata has the following format.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
BLOBVersion																															
BLOBElementCount																															
BLOBElement (variable)																															
...																															

**BLOBVersion (4 bytes):** The DFS metadata format version stored as an unsigned, 32-bit, **little-endian** integer. This MUST always be set to 0.

**BLOBElementCount (4 bytes):** The number of <BLOBElement> elements that immediately follow this field in the DFS metadata stored as an unsigned, 32-bit, little-endian integer.

**BLOBElement (variable):** A variable number of [DFSNamespaceElementBLOB](#) structures, which immediately follow the BLOBElementCount. Each DFSNamespaceElementBLOB contains descriptive information about a DFS site, root, or link. The format and size of each DFSNamespaceElementBLOB depend on the information contained in it.

### 2.3.3.1.1 DFSNamespaceElementBLOB

A DFSNamespaceElementBLOB contains information about a DFS root or a DFS link, or for mapping a server to its site name.

The DFS metadata of a valid DFS namespace MUST consist of one [DFSNamespaceRootBLOB](#) for the DFS root and one DFSNamespaceLinkBLOB for each DFS link in the DFS namespace. There MUST no more than one [SiteInformationBLOB](#). For more information on SiteInformationBLOB, see section [2.3.3.1.1.4](#).

No alignment padding requirements exist for any of a BLOB's fields, unless otherwise specified.

Each DFSNamespaceElementBLOB contains the following data elements. The first three fields are standard for all DFSNamespaceElementBLOB structures. Following those fields are additional fields that are specific to the type of DFSNamespaceElementBLOB, in the format of a DFSNamespaceRootBLOB, a DFSNamespaceLinkBLOB, or a SiteInformationBLOB.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
BLOBNameSize											BLOBName (variable)																				
...																															
BLOBDataSize																															
BLOBData (variable)																															
...																															

**BLOBNameSize (2 bytes):** The size of the **BLOBName**, in bytes, stored as an unsigned, 16-bit, little-endian integer.

**BLOBName (variable):** The name of the DFSNamespaceElementBLOB, stored as a string of Unicode characters.

Value	Meaning
SiteInformationBLOB "siteroot"	A string of Unicode characters that forms the literal "siteroot". <a href="#">&lt;11&gt;</a>
DFSNamespaceRootBLOB "domainroot"	A string of Unicode characters that forms the literal "domainroot".
DFSNamespaceLinkBLOB "domainroot\<GUIDString>"	A string of Unicode characters that forms the literal "domainroot\<GUIDString>", where <GUIDString> represents the string form of a GUID, as specified in <a href="#">[RFC4122]</a> , section 3. The GUID found in the link's ID BLOB MUST be used to create this.

**BLOBDataSize (4 bytes):** The length of the BLOB in the **BLOBData** field, stored as an unsigned, 32-bit, little-endian integer. The value of this field **MUST** be used to determine the start of the next DFSNamespaceElementBLOB.

**BLOBData (variable):** Data specific to the type of BLOB described, in the form of a DFSNamespaceRootBLOB, DFSNamespaceLinkBLOB, or SiteInformationBLOB.

The following sections specify the format of the DFSNamespaceRootBLOB, DFSNamespaceLinkBLOB, and SiteInformationBLOB.

### 2.3.3.1.1.1 DFSNamespaceRootBLOB or DFSNamespaceLinkBLOB

At most, only one DFSNamespaceRootBLOB can contain information about the DFS namespace root. One DFSNamespaceLinkBLOB exists for each DFS link in the namespace.

Each DFSNamespaceRootBLOB or DFSNamespaceLinkBLOB **MUST** have the following:

- One BLOB containing the name and other information about the DFS namespace root or DFS link. This is the [DFSRootOrLinkIDBLOB](#), as specified in section [2.3.3.1.1.2](#).
- One BLOB containing the DFS targets of the DFS root or DFS link. This is the [DFSTargetListBLOB](#), as specified in section [2.3.3.1.1.3](#).
- One reserved BLOB.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
DFSRootOrLinkIDBLOB (variable)																															
...																															
DFSTargetListBLOBSize																															
DFSTargetListBLOB (variable)																															
...																															
ReservedBLOBSize																															
ReservedBLOB																															
ReferralTTL																															

**DFSRootOrLinkIDBLOB (variable):** A BLOB that contains identification and status information for this DFS root or DFS link.

**DFSTargetListBLOBSize (4 bytes):** The size, in bytes, of the BLOB in the **TargetListBLOB** field that immediately follows this field. The DFSTargetListBLOBSize is stored as an unsigned, 32-bit, little-endian integer.

**DFSTargetListBLOB (variable):** A BLOB that contains the list of targets for the DFS root or DFS link.

**ReservedBLOBSize (4 bytes):** The size, in bytes, of the BLOB in the **ReservedBLOB** field that immediately follows this field. The **ReservedBLOBSize** is stored as an unsigned, 32-bit, little-endian integer and **MUST** be 4.

**ReservedBLOB (4 bytes):** When creating a new DFSNamespaceRootBLOB or DFSNamespaceLinkBLOB, this **ReservedBLOB** **MUST** be zero-filled. When updating an existing DFSNamespaceRootBLOB or DFSNamespaceLinkBLOB, the contents of this **ReservedBLOB** **MUST** be preserved.

**ReferralTTL (4 bytes):** The referral time-out value, in seconds, for the DFS root or DFS link. The **ReferralTTL** is stored as an unsigned, 32-bit, little-endian integer.

### 2.3.3.1.1.2 DFSRootOrLinkIDBLOB

This BLOB contains name and other information about the DFS namespace root or the DFS link.

- If the PKT\_ENTRY\_TYPE\_REFERRAL\_SVC (0x00000080) bit is set in the **Type** field, then this BLOB describes the DFS root and is, hence, part of the [DFSNamespaceRootBLOB](#).
- If the PKT\_ENTRY\_TYPE\_REFERRAL\_SVC (0x00000080) bit is not set in the **Type** field, then this BLOB describes a link and is, hence, part of the DFSNamespaceLinkBLOB.

Version

**RootOrLinkGuid (16 bytes):** A GUID that identifies the DFS root or the DFS link. It is used to generate the name "\\<domainroot>\<GUIDString>" in the **BLOBName** field of the DFSNamespaceLinkBLOB, where <GUIDString> represents the string form of the GUID, as specified in [\[RFC4122\]](#), section 3.

**PrefixSize (2 bytes):** The size, in bytes, of the **Prefix** field, stored as an unsigned, 16-bit, little-endian integer.

**Prefix (variable):** The name of the DFS namespace root or the DFS link. The **Prefix** is stored as a string of Unicode characters and MUST be a UNC path string with one leading backslash, instead of the usual two, without a null termination.

**ShortPrefixSize (2 bytes):** The size, in bytes, of the **ShortPrefix** field, stored as an unsigned, 16-bit, little-endian integer.

**ShortPrefix (variable):** The name of the DFS namespace root or the DFS link, stored as a string of Unicode characters. This MUST be a UNC path string with one leading backslash, instead of the usual two, without a null termination. The string MAY be the same as that in the **Prefix** field or its **8.3 name**.<12>

**Type (4 bytes):** A bit field, stored as 32-bits in little-endian order, which describes this BLOB.

For domainv1 roots, the **Type** field parallels the functionality of the **msDFS-Propertiesv2** attribute used for domainv2-based DFS namespaces (see section [2.3.4.2](#)) and domainv2-based DFS links (see section [2.3.4.3](#)).

Value	Meaning
PKT_ENTRY_TYPE_DFS 0x00000001	This value is reserved and the <b>Type</b> field MUST always be set with this value.
PKT_ENTRY_TYPE_OUTSIDE_MY_DOM 0x00000010	The <b>DFS interlink</b> property. This MUST be set only when at least one DFS link target points to another DFS namespace. This MUST NOT be set for a DFS root.
PKT_ENTRY_TYPE_INSITE_ONLY 0x00000020	The DFS in-site referral mode property. When set, instructs the DFS server to enable the DFS in-site referral mode.
PKT_ENTRY_TYPE_COST_BASED_SITE_SELECTION	The DFS referral site costing property. Enables DFS referral site costing. This

Value	Meaning
0x00000040	SHOULD be supported.<13>
PKT_ENTRY_TYPE_REFERRAL_SVC 0x00000080	This identifies the DFS namespace root.
PKT_ENTRY_TYPE_ROOT_SCALABILITY 0x00000200	The DFS root scalability mode property. This enables DFS root scalability mode. This SHOULD be supported.<14>
PKT_ENTRY_TYPE_TARGET_FAILBACK 0x00008000	The DFS client target failback property. This enables DFS client target failback for targets of this root or link. This SHOULD be supported.<15>

Undefined bit positions MUST be set to 0 on writes and ignored on reads.

**State (4 bytes):** The status of the DFS root or DFS link stored as an unsigned, 32-bit, little-endian integer. The DFS\_VOLUME\_STATES bitmask (0x0000000F) MUST be used to access the following DFS root or DFS link state from this field. For more information about some of these states, see section [2.2.2.13](#).

Value	Meaning
DFS_VOLUME_STATE_OK 0x00000001	The DFS root or DFS link state is okay.
RESERVED 0x00000002	This value is reserved and MUST NOT be used.
DFS_VOLUME_STATE_OFFLINE 0x00000003	The DFS link is offline and not available for use.
DFS_VOLUME_STATE_ONLINE 0x00000004	The DFS link is online and available for use.

Undefined bit positions of this field MUST be set to 0 on writes and ignored on reads.

**CommentSize (2 bytes):** The size, in bytes, of the **Comment** field and stored as an unsigned, 16-bit, little-endian integer.

**Comment (variable):** A string of Unicode characters whose size in bytes is specified by the **CommentSize** field. The **Comment** field is associated with the namespace root or link and is for informational purposes. The comment is meant for human consumption and does not affect server functionality.

**PrefixTimeStamp (8 bytes):** The time of the last **Prefix** field modification, stored as **FILETIME**. This SHOULD be set to the last modification time of this BLOB.

**StateTimeStamp (8 bytes):** The time of the last **State** field modification, stored as FILETIME. This SHOULD be set to the last modification time of this BLOB.

**CommentTimeStamp (8 bytes):** The time of the last **Comment** field modification, stored as FILETIME. This SHOULD be set to the last modification time of this BLOB.

**Version (4 bytes):** The version number of DFSRootOrLinkIDBLOB, stored as an unsigned, 32-bit, little-endian integer. When creating a new DFSRootOrLinkIDBLOB, this MUST be set to 0x00000003. When updating an existing DFSRootOrLinkIDBLOB, the existing value MUST be preserved.

### 2.3.3.1.1.3 DFSTargetListBLOB

The DFSTargetListBLOB contains information about all of the targets of the DFS root or DFS link.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
TargetCount																															
TargetEntryBLOB (variable)																															
...																															

**TargetCount (4 bytes):** The number of [TargetEntryBLOB](#) fields contained in this BLOB, stored as an unsigned, 32-bit, little-endian integer.

**TargetEntryBLOB (variable):** A BLOB that contains metadata for a DFS target.

#### 2.3.3.1.1.3.1 TargetEntryBLOB

The TargetEntryBLOB holds metadata for the DFS target of a root or a link.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
TargetEntrySize																															
TargetTimeStamp																															
...																															
TargetState																															
TargetType																															
ServerNameSize																ServerName (variable)															
...																															
ShareNameSize																ShareName (variable)															
...																															

**TargetEntrySize (4 bytes):** The size, in bytes, of this target entry, starting from the **TargetTimeStamp** field, and stored as an unsigned, 32-bit, little-endian integer.

**TargetTimeStamp (8 bytes):** If bits 9 through 63 contain nonzero values, this field encodes the last modification time of this target entry, stored as FILETIME. In this case the **PriorityRank** and **PriorityClass** members, discussed below, are considered to logically contain zero if referenced by an implementation.

If bits 9 through 63 are zero, the 64 bits of the **TargetTimeStamp** has the following format:

0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1	2	3	4	5	6	7	8	9	0	1
PriorityRank					PriorityClasses			High56Bits																							
...																															

**PriorityRank (5 bits):** The priority rank of a target, ranging in value from 0x00 to 0x1F, where 0x00 is the highest rank.

**PriorityClass (3 bits):** The priority class of a target. One of the following values.

Value	Meaning
DFS_TARGET_PRIORITY_CLASS_SITE_COST_NORMAL 0x0	See DfsSiteCostNormalPriorityClass in section <a href="#">2.2.2.8</a> .
DFS_TARGET_PRIORITY_CLASS_GLOBAL_HIGH 0x1	See DfsSGlobalHighPriorityClass in section <a href="#">2.2.2.8</a> .
DFS_TARGET_PRIORITY_CLASS_SITE_COST_HIGH 0x2	See DfsSiteCostHighPriorityClass in section <a href="#">2.2.2.8</a> .
DFS_TARGET_PRIORITY_CLASS_SITE_COST_LOW 0x3	See DfsSiteCostLowPriorityClass in section <a href="#">2.2.2.8</a> .
DFS_TARGET_PRIORITY_CLASS_GLOBAL_LOW 0x4	see DfsGlobalLowPriorityClass in section <a href="#">2.2.2.8</a> .

**High56Bits (7 bytes):** Set to zero.

**TargetState (4 bytes):** The state of this target, stored as an unsigned, 32-bit, little-endian integer. The mask 0x0000000F is used to extract a bit field that contains one of the following valid state values.

Value	Meaning
DFS_STORAGE_STATE_OFFLINE 0x00000001	This target is offline and unavailable for use.
DFS_STORAGE_STATE_ONLINE 0x00000002	This target is online and available for use.

Value	Meaning
DFS_STORAGE_STATE_ACTIVE 0x00000004	This target is active.

**TargetType (4 bytes):** The type of target, stored as an unsigned, 32-bit, little-endian integer bit field. This SHOULD be set to 0x00000002. <16>

**ServerNameSize (2 bytes):** The size, in bytes, of the **ServerName** field, stored as an unsigned 16-bit, little-endian integer.

**ServerName (variable):** An array of Unicode characters that contains the DFS target server host name. The size of the array is given in the **ServerNameSize** field.

**ShareNameSize (2 bytes):** The size, in bytes, of the **ShareName**, stored as an unsigned, 16-bit, little-endian integer.

**ShareName (variable):** An array of Unicode characters that contains the DFS target share name.

### 2.3.3.1.1.4 SiteInformationBLOB

The SiteInformationBLOB contains the mapping from a DFS target host name to its site name. There MUST be no more than one BLOB of this type. This BLOB contains zero or more [SiteEntryBLOBs](#).

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
SiteTableGuid																															
...																															
...																															
...																															
SiteEntryCount																															
SiteEntryBLOB (variable)																															
...																															

**SiteTableGuid (16 bytes):** The GUID that uniquely identifies the SiteInformationBLOB.

**SiteEntryCount (4 bytes):** The number of SiteEntryBLOBs in the SiteEntryBLOB field, stored as an unsigned, 32-bit, little-endian integer. This MAY be zero. <17><18>

**SiteEntryBLOB (variable):** Zero or more BLOBs. Each BLOB contains the site of a root target or link target server in the DFS namespace.

### 2.3.3.1.1.4.1 SiteEntryBLOB

This BLOB contains a host name whose site information is specified by the [SiteNameInfoBLOB](#) (for more information, see section [2.3.3.1.1.4.1.1](#)).

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
ServerNameSize																ServerName (variable)															
...																															
SiteNameInfoCount																															
SiteNameInfoBLOB (variable)																															
...																															

**ServerNameSize (2 bytes):** The size, in bytes, of the **ServerName** field, stored as an unsigned, 16-bit, little-endian integer.

**ServerName (variable):** A string of Unicode characters representing the DFS target host name.

**SiteNameInfoCount (4 bytes):** The number of SiteNameInfoBLOBs in the SiteNameInfoBLOB field, stored as an unsigned, 32-bit, little-endian integer.

**SiteNameInfoBLOB (variable):** The BLOB containing the site name of the server in the SiteEntryBLOB.

#### 2.3.3.1.1.4.1.1 SiteNameInfoBLOB

The SiteNameInfoBLOB contains the name of a site to which a server belongs.

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
Flags																															
SiteNameSize																SiteName (variable)															
...																															

**Flags (4 bytes):** This MUST be set to 0 on write. MUST be ignored on read.

**SiteNameSize (2 bytes):** The size, in bytes, of the **SiteName** field, stored as an unsigned, 16-bit, little-endian integer.

**SiteName (variable):** A string of Unicode characters representing the directory services site name of the server. The case of the **site** name, as provided by directory services, MUST be preserved when storing in this field.

## 2.3.4 Schema for Domainv2-Based DFS Namespace

Each domainv2-based DFS namespace has one DFS namespace anchor LDAP entry, one DFS namespace LDAP entry below it, and one LDAP entry per DFS link in the namespace under the DFS namespace LDAP entry. The following sections specify the mandatory and optional attributes of the object classes.

### 2.3.4.1 LDAP Entry for Domainv2-Based DFS Namespace Anchor

Each domainv2-based DFS namespace under the DFS configuration container has a DFS namespace anchor LDAP entry.

This object has a single attribute: **msDFS-SchemaMajorVersion**. This attribute is an integer value containing the major version number of the supported DFS metadata format.

The object class of the LDAP entry corresponding to the domainv2-based DFS namespace anchor is `ms-DFS-Namespace-Anchor`, and its schema is specified in [\[MS-ADSC\]](#). The schema of the `msDFS-SchemaMajorVersion` attribute is specified in [\[MS-ADA2\]](#). Future revisions of the DFS namespace will retain this LDAP entry to provide the DFS metadata version information of the DFS namespace.

### 2.3.4.2 LDAP Entry for Domainv2-Based DFS Namespace

A DFS namespace LDAP entry exists for each domainv2-based DFS namespace under the DFS namespace anchor LDAP entry.

This object has the following attributes. The schemas for these attributes are specified in [\[MS-ADA2\]](#).

Attribute	Description
<code>msDFS-SchemaMajorVersion</code>	An integer value that contains the major version number of the DFS metadata format supported.
<code>msDFS-SchemaMinorVersion</code>	An integer value that contains the minor version number of the DFS metadata format supported. The <b>rangeLower</b> attribute of the attribute schema's LDAP entry contains 0, and the <b>rangeUpper</b> attribute of the attribute schema's LDAP entry contains the highest minor version number supported.
<code>msDFS-NamespaceIdentityGUIDv2</code>	This is the time-stable identifier for a DFS namespace. It is a binary value set at DFS namespace creation time whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes.
<code>msDFS-GenerationGUIDv2</code>	A binary value whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes. This time-stable identifier is overwritten anytime the LDAP entry corresponding to the DFS namespace or the DFS link is modified. This is reserved for future use and MUST NOT be currently used.
<code>msDFS-LastModifiedv2</code>	A time string format defined by ASN.1 standards, as specified in <a href="#">[X680]</a> . The <b>Coordinated Universal Time (UTC)</b> in the form <code>YYYYMMDDHHMMSS.OZ"OZ"</code> indicates no time differential. This attribute is updated each time the DFS root is updated.
<code>msDFS-Ttlv2</code>	A 32-bit signed integer that is interpreted as an unsigned referral Time to Live (TTL), in seconds.

Attribute	Description
msDFS-TargetListv2	This attribute stores the DFS target information. The information is stored as an XML document that contains a list of targets for the root as well as attributes associated with each target. The maximum size is 2 MB. For the XML schema of the XML document, see <a href="#">Appendix C</a> .
msDFS-Propertiesv2	This is a multivalued attribute that contains attributes corresponding to the DFS root. Each attribute is a case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2).
msDFS-Commentv2	An optional attribute that contains a comment associated with the DFS namespace root. A String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2).

Attribute values for **msDFS-Propertiesv2** are described in the following table. A server **MUST** ignore unrecognized attribute values when reading the metadata. A server **SHOULD** preserve unrecognized attribute values when writing the metadata. Note that they are fixed strings. They have a more general appearance, but a string comparison is sufficient to analyze them. The absence of an attribute value in the **msDFS-Propertiesv2** attribute indicates that the corresponding property is not set.

For domainv2-based DFS namespaces, the **msDFS-Propertiesv2** attribute parallels the functionality of the [DFSRootOrLinkIDBLOB](#) (section [2.3.3.1.1.2](#)) **Type** field used for domainv1-based namespaces.

Attribute Value	Description
ABDE=on	The Access Based Directory Enumeration (ABDE) mode property. Enables ABDE mode.
InsiteReferral=on	The DFS in-site referral mode property. When set, instructs the DFS server to enable the DFS in-site referral mode.
ReferralSiteCosting=on	The DFS referral site costing property. Enables DFS referral site costing and <b>SHOULD</b> be supported. <a href="#">&lt;20&gt;</a>
RootScalability=on	The DFS root scalability mode property. This enables DFS root scalability mode and <b>SHOULD</b> be supported. <a href="#">&lt;21&gt;</a>
TargetFailback=on	The DFS client target failback property. This enables DFS client target failback for targets of this root and <b>SHOULD</b> be supported. <a href="#">&lt;22&gt;</a>
State=Okay	The DFS root is available for referral requests.

The following attributes are mandatory: msDFS-SchemaMajorVersion, msDFS-SchemaMinorVersion, msDFS-NamespaceIdentityGUIDv2, msDFS-GenerationGUIDv2, msDFS-LastModifiedv2, msDFS-Ttlv2, msDFS-TargetListv2, and msDFS-Propertiesv2.

The msDFS-Commentv2 attribute is optional.

The object class of the LDAP entry corresponding to the domainv2-based DFS namespace is msDFS-NameSpacev2, and its schema is specified in [\[MS-ADSC\]](#).

### 2.3.4.3 LDAP Entry for Domainv2-Based DFS Link

One LDAP entry exists for each DFS link in the namespace under the DFS namespace LDAP entry.

This object has the following attributes. The schemas for these attributes are specified in [\[MS-ADA2\]](#).

Attribute	Description
msDFS- NamespaceIdentityGUIDv2	This is the time-stable identifier for the DFS namespace containing the link, and matches the value specified in the namespace LDAP entry. It is a binary value set at DFS namespace creation time whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes.
msDFS-LinkIdentityGUIDv2	This is the time-stable identifier for a DFS link. It is a binary value set at DFS link creation time whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes. This value is retained in the dynamic object created when the link is deleted.
msDFS-GenerationGUIDv2	A binary value whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes. This time-stable identifier is overwritten anytime the LDAP entry corresponding to the DFS namespace or the DFS link is modified.  This is reserved for future use and MUST NOT be currently used.
msDFS-LinkPathv2	A case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2) that is the DFS root-relative path to the DFS link reparse point. To simplify LDAP searches, path separators are forward slashes (/) instead of backward slashes (\).
msDFS- ShortNameLinkPathv2	A case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2) that is the DFS namespace root-relative path to the DFS link reparse point in short name form. To simplify LDAP searches, path separators are forward slashes (/) instead of backward slashes (\).  This is reserved for future use and MUST NOT be currently used.
msDFS- LinkSecurityDescriptorv2	A self-relative security descriptor associated with a DFS link. This attribute is used for Access Based Directory Enumeration (ABDE) support.
msDFS-LastModifiedv2	A time string format defined by ASN.1 standards. The UTC time in the form YYYYMMDDHHMMSS.0Z"0Z" indicates no time differential.  This attribute is updated each time the DFS link is updated.
msDFS-Ttlv2	A 32-bit signed integer that is interpreted as an unsigned referral TTL, in seconds.
msDFS-TargetListv2	This attribute stores the DFS target information. The information is stored as an XML document that contains a list of targets for the link as well as attributes associated with each target. The maximum size is 2 MB. For the XML schema of the XML document, see <a href="#">Appendix C</a> .
msDFS-Propertiesv2	This is a multivalued attribute that contains attributes corresponding to the DFS link (not individual targets). Each attribute is a case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2).
msDFS-Commentv2	An optional attribute that contains a comment associated with the DFS link. A String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2).

Attribute values for **msDFS-Propertiesv2** are described in the following table. A server MUST ignore unrecognized attribute values when reading the metadata. A server SHOULD [<23>](#) preserve unrecognized attribute values when writing the metadata. Note that they are fixed strings. While they have a more general appearance, a string comparison is sufficient to analyze them. The

absence of an attribute value in the **msDFS-Propertiesv2** attribute indicates that the corresponding property is not set.

For domainv2-based DFS links, the **msDFS-Propertiesv2** attribute parallels the functionality of the [DFSRootOrLinkIDBLOB](#) (section [2.3.3.1.1.2](#)) **Type** field used for domainv1-based DFS links.

Attribute Value	Description
InsiteReferral=on	The DFS in-site referral mode property. When set, instructs the DFS server to enable the DFS in-site referral mode.
ReferralSiteCosting=on	The DFS referral site costing property. Enables DFS referral site costing. This SHOULD be supported. <a href="#">&lt;24&gt;</a>
TargetFailback=on	The DFS client target failback property. This enables DFS client target failback for targets of this link. This SHOULD be supported. <a href="#">&lt;25&gt;</a>
Interlink=on	The DFS interlink property. This MUST be set only when at least one DFS link target points to another domain-based DFS namespace.
State=Okay OR State=Offline OR State=Online	The state of the <b>DFS link</b> . "State=Okay" means that the <b>DFS link</b> is available for referral requests. "State=Offline" means that the <b>DFS link</b> is offline and none of the DFS targets will be included in the referral response. "State=Online" means that the <b>DFS link</b> is online and available for referral requests.

The following attributes are mandatory: **msDFS-NamespaceIdentityGUIDv2**, **msDFS-LinkIdentityGUIDv2**, **msDFS-GenerationGUIDv2**, **msDFS-LinkPathv2**, **msDFS-LastModifiedv2**, **msDFS-Ttlv2**, **msDFS-TargetListv2**, and **msDFS-Propertiesv2**.

The following attributes are optional: **msDFS-ShortNameLinkPathv2**, **msDFS-LinkSecurityDescriptorv2**, and **msDFS-Commentv2**.

The object class of the LDAP entry corresponding to a DFS link in a domainV2-based DFS namespace is **msDFS-Linkv2**, and its schema is specified in [\[MS-ADSC\]](#).

#### 2.3.4.4 LDAP Entry for Domainv2-Based Deleted Link

Only one LDAP entry corresponds to a deleted link in a domainv2-based DFS namespace. This is a dynamic object.

This object has the following attributes. The schemas for these attributes are specified in [\[MS-ADA2\]](#).

Attribute	Description
msDFS- NamespaceIdentityGUIDv2	This is the time-stable identifier for the DFS namespace containing the link, and it matches the value specified in the namespace LDAP entry. It is a binary value set at DFS namespace creation time whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes.
msDFS-LinkIdentityGUIDv2	This is the time-stable identifier for a DFS link. It is a binary value set at DFS link creation time whose size is specified by the <b>rangeLower</b> and <b>rangeUpper</b> attributes. This value is retained in the dynamic object created when the link is deleted.

Attribute	Description
msDFS-LastModifiedv2	A time string format defined by ASN.1 standards. The UTC time in the form YYYYMMDDHHMMSS.0Z"0Z" indicates no time differential. This attribute is updated each time the DFS link entry is updated.
msDFS-LinkPathv2	A case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2) that is the DFS root-relative path to the DFS link reparse point. To simplify LDAP searches, path separators are forward slashes (/) instead of backward slashes (\).
msDFS-Commentv2	An optional attribute that contains a comment associated with the DFS namespace link. A case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2).
msDFS-ShortNameLinkPathv2	A case-insensitive String(Unicode) (see <a href="#">[MS-ADTS]</a> section 3.1.1.2.2.2) that is the DFS namespace root-relative path to the DFS link reparse point in short name form. To simplify LDAP searches, path separators are forward slashes (/) instead of backward slashes (\). This is reserved for future use and MUST NOT be currently used.

The following attributes are mandatory: msDFS-NamespaceIdentityGUIDv2, msDFS-LinkIdentityGUIDv2, msDFS-LastModifiedv2, and msDFS-LinkPathv2.

The following attributes are optional: msDFS-Commentv2 and msDFS-ShortNameLinkPathv2.

The object class of the LDAP entry corresponding to a DFS link in a domainv2-based DFS namespace is msDFS-DeletedLinkv2, and its schema is as specified in [\[MS-ADSC\]](#).

## 3 Protocol Details

### 3.1 Server Details

#### 3.1.1 Abstract Data Model

This section describes a conceptual model of a possible data organization that an implementation could maintain in order to participate in this protocol. This organization is provided to facilitate the explanation of how the protocol behaves. This specification does not mandate that implementations adhere to this model, as long as their external behavior is consistent with that described in this document. The following data items are implemented on the server side and are specific to this protocol:

- **PDCRoleHolder:** For servers of domain-based DFS namespaces, this is the PDC corresponding to the server's domain.
- **DFSMetadataCache:** DFS metadata of DFS namespaces for which the server is a root target MAY [<26>](#) be cached as an optimization.

**Note** The preceding conceptual data can be implemented using a variety of techniques. There are no limitations on data implementation.

##### 3.1.1.1 Global

The following element is global.

**NamespaceList:** A list of namespaces hosted by the server. Each entry is a tuple of **<NamespaceName, Namespace>**, indexed by the **NamespaceName**, as specified in section [3.1.1.2](#).

##### 3.1.1.2 Per Namespace

The following are the elements of a **Namespace** element:

**Namespace.NamespaceName:** The DFS namespace name.

**Namespace.NamespaceType:** Type of the DFS namespace – stand-alone, domainv1-based or domainv2-based.

**Namespace.GenerationGUID:** A GUID used as a generation number to detect changes to the DFS metadata. This **MUST** be updated whenever the metadata of the DFS namespace is changed.

**Namespace.NamespaceElementsList:** List of the DFS namespace elements as described in section [3.1.1.3](#).

##### 3.1.1.3 Per NamespaceElement

The **NamespaceElement** represents a DFS root or a DFS link and has the following parameters:

**NamespaceElement.IdentityGUID:** A GUID that identifies the DFS namespace element.

**NamespaceElement.Prefix:** Name of the DFS namespace element.

**NamespaceElement.Properties:** Set of properties that are applicable for the DFS namespace element, as specified for **PropertyFlags** in section [2.2.3.5](#).

**NamespaceElement.State:** State of the DFS namespace element, as specified for **State** in section [2.2.3.2](#).

**NamespaceElement.Comment:** Comment associated with the DFS namespace element.

**NamespaceElement.ReferralTTL:** The referral time-out value, in seconds, for the DFS namespace element.

**NamespaceElement.SecurityDescriptor:** SecurityDescriptor to be associated with the DFS namespace element. This is needed only for the DFS link of a stand-alone or domainv2-based DFS namespace.

**NamespaceElement.TargetsList:** List of targets for the DFS namespace element. Each element in the list is as described in section [3.1.1.4](#).

#### 3.1.1.4 Per TargetsList

The following are the elements of a **TargetsList**.

**TargetsList.TargetCount:** Number of targets for the DFS namespace element.

**TargetsList.Target :** Metadata of the target. This is as described in the section [3.1.1.5](#).

#### 3.1.1.5 Per Target

The following are the elements of a **Target** element.

**Target.TargetState:** State of the target, as specified for State in section [2.2.4.6](#).

**Target.PriorityRank:** Priority rank of the target, as specified for TargetPriorityRank in section [2.2.2.7](#).

**Target.PriorityClass:** Priority class of the target, as specified in section [2.2.2.8](#).

**Target.ServerName:** The DFS target host name.

**Target.ShareName:** The DFS target share name.

### 3.1.2 Timers

No protocol timers are required beyond those used internally by RPC to implement resiliency to network outages, as specified in [\[MS-RPCE\]](#).

### 3.1.3 Initialization

The server MUST listen on the well-known endpoint defined for this RPC interface, as specified in section [2.1](#).

Information about DFS namespaces that the server hosts SHOULD be obtained from a local information store such as the registry. An entry MUST be created for each namespace in the **NamespaceList**. If the server is hosting any stand-alone namespaces, the metadata for that namespace MUST be initialized into the corresponding **Namespace** in the **NamespaceList**. If the server is joined to a domain and is hosting at least one DFS namespace, it MAY [<27>](#) determine the PDC for the domain and initialize PDCRoleHolder. As a performance optimization, it MAY [<28>](#) preload the DFSMetadataCache with the DFS metadata of the DFS namespaces for which it is acting as a root target.

### 3.1.4 Message Processing Events and Sequencing Rules

When any RPC method is received for a domain-based DFS namespace that is hosted by the server, the server MUST first check whether the DFS namespace is up-to-date with any changes that may have happened on it. This check MUST be done against the PDC. When any changes are detected, the server MUST first bring the namespace it hosts up-to-date and then process the RPC method received. The details of this operation are implementation-specific.

For a domainv1-based DFS namespace, if the **pKTGuid** value matches the cached value, the server MAY work on a cached copy of the **pKT** attribute. The update operation MUST be committed by issuing LDAP writes for both the updated **pKT** attribute and a newly generated **pKTGuid** attribute. Using the same LDAP update operation for both attributes ensures atomicity of the update.

For non-update operations in domain-based DFS namespaces, DFS servers MAY retrieve DFS metadata from any DC within the domain. For update operations in domain-based DFS namespaces, DFS servers MUST retrieve and store DFS metadata on the PDC.

Unless noted otherwise, DFS servers MUST process host names as case-insensitive string literals. The DFS server MUST NOT, for example, consider a DNS-conformant host name (as specified in [\[RFC1034\]](#)) and an IP address as equivalent, even if the host name resolves via DNS to the IP address.

This protocol uses Win32 error codes. These values are taken from the Windows error number space, as specified in [\[MS-ERREF\]](#). Vendors SHOULD reuse those values with their indicated meanings. Choosing any other value runs the risk of future collisions. <29>

The remainder of this section describes the methods used in the DFS: Namespace Management Protocol. The following table lists opnum values associated with the methods described in this document, as well as the section where each is described.

Methods in RPC Opnum Order

Method	Description
<a href="#">NetrDfsManagerGetVersion</a>	A basic method that returns the version number of the DFS server. Opnum: 0
<a href="#">NetrDfsAdd</a>	A basic method that creates a new DFS link or that adds a new target to an existing link of a DFS namespace. Opnum: 1
<a href="#">NetrDfsRemove</a>	A basic method that removes a link or a link target from a DFS namespace. Opnum: 2
<a href="#">NetrDfsSetInfo</a>	A basic method that sets or modifies information relevant to a specific DFS root, DFS root target, DFS link, or DFS link target. Opnum: 3
<a href="#">NetrDfsGetInfo</a>	A basic method that returns information about a DFS root, a DFS link, or a DFS namespace. Opnum: 4
<a href="#">NetrDfsEnum</a>	A basic method that enumerates the DFS roots hosted on

Method	Description
	a server or the DFS links of a namespace on the server. Opnum: 5
<a href="#">NetrDfsMove</a>	A basic method that renames or moves one or more DFS links. <30> Opnum: 6
<b>Opnum7NotUsedOnWire</b>	Reserved for local use. Opnum: 7
<b>Opnum8NotUsedOnWire</b>	Reserved for local use. Opnum: 8
<b>Opnum9NotUsedOnWire</b>	Reserved for local use. Opnum: 9
<a href="#">NetrDfsAddFtRoot</a>	A root target method that creates a new domainv1-based DFS namespace or that adds a root target to an existing namespace. Opnum: 10
<a href="#">NetrDfsRemoveFtRoot</a>	A root target method that removes a root target from a domain-based DFS namespace or that removes a domain-based DFS namespace. Opnum: 11
<a href="#">NetrDfsAddStdRoot</a>	A stand-alone namespace method that creates a new stand-alone DFS namespace. Opnum: 12
<a href="#">NetrDfsRemoveStdRoot</a>	A stand-alone namespace method that deletes a stand-alone DFS namespace. Opnum: 13
<a href="#">NetrDfsManagerInitialize</a>	A basic method that instructs the DFS server to discard its current state and to reinitialize itself from its stored configuration settings. Opnum: 14
<a href="#">NetrDfsAddStdRootForced</a>	A stand-alone namespace method that creates a new stand-alone DFS namespace without verifying the existence of the DFS root target share. Opnum: 15
<a href="#">NetrDfsGetDcAddress</a>	A domain-based namespace method that returns the host name of the DC for the client to use during the following processes: creating a domain-based DFS namespace, adding a root target to a domain-based DFS namespace, removing a root target from a domain-based DFS namespace, or removing a domain-based DFS namespace. Opnum: 16
<a href="#">NetrDfsSetDcAddress</a>	A domain-based namespace method that instructs a DFS server to use a specific DC for DFS metadata access in a

Method	Description
	domain-based DFS namespace. Opnum: 17
<a href="#">NetrDfsFlushFtTable</a>	A root target method that instructs the DFS server on a DC to purge a domain-based DFS entry from its referral cache. Opnum: 18
<a href="#">NetrDfsAdd2</a>	An extended method that creates a new DFS link or that adds a new target to an existing link of a DFS namespace. Opnum: 19
<a href="#">NetrDfsRemove2</a>	An extended method that removes a link or a link target. Opnum: 20
<a href="#">NetrDfsEnumEx</a>	An extended method that enumerates DFS roots hosted on a machine or DFS links of a namespace. Opnum: 21
<a href="#">NetrDfsSetInfo2</a>	An extended method that sets or modifies the information that is associated with a DFS root, a DFS root target, a DFS link, or a DFS link target. Opnum: 22
<a href="#">NetrDfsAddRootTarget</a>	A basic method that creates a stand-alone DFS namespace, a domainv1-based DFS namespace, or a domainv2-based DFS namespace.<31> Opnum: 23
<a href="#">NetrDfsRemoveRootTarget</a>	A basic method that deletes a stand-alone DFS namespace, a domainv1-based DFS namespace, or a domainv2-based DFS namespace.<32> Opnum: 24
<a href="#">NetrDfsGetSupportedNamespaceVersion</a>	A basic method that determines the supported DFS metadata version number. This method is useful in determining an appropriate version number to pass to the NetrDfsAddRootTarget() method.<33> Opnum: 25

In the preceding table, the term "Reserved for local use" means that the client MUST NOT send the opnum, and the server behavior is undefined <34> because it does not affect interoperability.

### 3.1.4.1 Basic Methods

#### 3.1.4.1.1 NetrDfsManagerInitialize (Opnum 14)

The **NetrDfsManagerInitialize** method instructs the DFS server to discard its current state and reinitialize itself from its stored configuration settings. The server SHOULD <35> choose to implement this method.

The **NetrDfsManagerInitialize** method has the following **Microsoft Interface Definition Language (MIDL)** syntax.

```

NET_API_STATUS NetrDfsManagerInitialize(
    [in, string] WCHAR* ServerName,
    [in] DWORD Flags
);

```

**ServerName:** The pointer to a null-terminated Unicode host name string of the DFS root target server or DC where the DFS service is to be reinitialized.

**Flags:** This parameter MUST be zero.

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000032 ERROR_NOT_SUPPORTED	Server does not support the requested operation.

If this method is implemented, the DFS server SHOULD [<36>](#) discard its current state and reinitialize itself from its stored configuration settings.

### 3.1.4.1.2 NetrDfsManagerGetVersion (Opnum 0)

The **NetrDfsManagerGetVersion** method returns the version number of the DFS server in use on the server.

The **NetrDfsManagerGetVersion** method has the following MIDL syntax.

```
DWORD NetrDfsManagerGetVersion();
```

This method has no parameters.

**Return Values:** This method MUST return one of the following values.

Return value	Description
0x00000001	The server MUST support stand-alone DFS namespaces and opnums from 0 through 5, inclusive. The server MAY support domain-based DFS namespaces and other opnums.
0x00000002	In addition to the preceding, the server MUST support domainv1-based DFS namespaces and opnums 10 through 22, inclusive. The server MAY support hosting more than one DFS namespace on the same server.
0x00000004	In addition to the preceding, the server MUST support hosting more than one DFS namespace on the same server and Level parameter value 200 of the

Return value	Description
	<a href="#">NetrDfsEnumEx</a> method. It SHOULD support opnum 6.
0x00000006	In addition to the preceding, the server MUST support domainv2-based DFS namespace and opnums 23 through 25, inclusive.

The clients MAY use the version information to determine the RPC methods that the DFS server supports. [<37><38><39><40><41>](#)

### 3.1.4.1.3 NetrDfsAdd (Opnum 1)

The **NetrDfsAdd** method creates a new DFS link or adds a new target to an existing link of a DFS namespace.

The **NetrDfsAdd (Opnum 1)** method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsAdd(
    [in, string] WCHAR* DfsEntryPath,
    [in, string] WCHAR* ServerName,
    [in, unique, string] WCHAR* ShareName,
    [in, unique, string] WCHAR* Comment,
    [in] DWORD Flags
);
```

**DfsEntryPath:** The pointer to a DFS link path that contains the name of an existing link when additional link targets are being added or the name of a new link is being created.

**ServerName:** The pointer to a null-terminated Unicode string that specifies the DFS link target host name.

**ShareName:** The pointer to a null-terminated Unicode DFS link target share name string. This may also be a share name with a path relative to the share, for example, "share1\mydir1\mydir2". When specified this way, each pathname component MUST be a directory.

**Comment:** The pointer to a null-terminated Unicode string that contains a comment associated with this root or link. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality. The comment MUST be ignored when adding a target to an existing link.

**Flags:** A value indicating the operation to perform. The following table lists such flags.

Value	Meaning
0x00000000	Create a new link or adds a new target to an existing link.
DFS_ADD_VOLUME 0x00000001	Create a new link in the DFS namespace if one does not already exist or fails if a link already exists.
DFS_RESTORE_VOLUME 0x00000002	Add a target without verifying its existence.

If a *Flags* value other than the bitwise-OR of the above values is provided, the server MUST return ERROR\_INVALID\_PARAMETER (0x00000057).

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000050 ERROR_FILE_EXISTS	The specified DFS link target already exists.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS root namespace does not exist.
0x00000032 ERROR_NOT_SUPPORTED	The method does not support a domain-based namespace.
0x00000906 NERR_NetNameNotFound	The DFS link target does not exist.

The [NetrDfsAdd](#) method SHOULD<42> support a domain-based DFS namespace. If it does not support a domain-based DFS namespace it MUST return ERROR\_NOT\_SUPPORTED.

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify whether the link to be added overlaps an existing link. If there is a link for which the specified *DfsEntryPath* parameter is a prefix, the server MUST return ERROR\_FILE\_EXISTS.

If the link to be added already exists, and DFS\_ADD\_VOLUME is set in the **Flags** field of the request, the server MUST return ERROR\_FILE\_EXISTS.

If the link to be added already exists, and DFS\_ADD\_VOLUME is not set in the **Flags** field of the request, the server MUST attempt to add a new link target to the link. If a target with the path specified by *ServerName* and *ShareName* was already added to the link, the server MUST return ERROR\_FILE\_EXISTS.

If DFS\_RESTORE\_VOLUME is not specified on the *Flags* parameter, the server MAY<43> choose to verify whether the link target exists. If DFS\_RESTORE\_VOLUME is specified, the server MUST NOT perform this test. If it performs the test and the link target does not exist, the server MUST fail the call with NERR\_NetNameNotFound.

The exact test the server performs to verify link target existence is implementation-defined. A server MAY,<44> for example, assume all link targets are administered through [\[MS-SRVS\]](#) section 3.1.4.10 and use **NetShareGetInfo** level 1005 to perform the test. Three reasons not to implement this test are that

- It may not be practical to determine the correct administration interface to query to perform the test.
- A link target server may export a share with a network protocol and administration interface that this server does not understand.
- A secured link target server may not permit this server to contact it.

The *Comment* parameter MUST be ignored when a target is added to an existing link.

The server SHOULD [<45>](#) create a new link without requiring the *DFS\_ADD\_VOLUME Flags* parameter.

The server MUST determine whether the specified link target refers to a domain-based namespace. If it does, this request is creating a DFS interlink. If it is creating an interlink and the link already exists, the server MUST return an implementation-defined failure value. For domain-based namespaces, the server MUST set the DFS interlink property as appropriate for the link for each type of domain-based namespace. See sections [2.3.3.1.1.2](#) and [2.3.4.3](#).

The server MUST synchronously update the following fields in the DFS metadata for a stand-alone DFS namespace.

Operation	DFS metadata changes required
Adding a new link	New <b>NamespaceElement</b> in <b>NamespaceElementsList</b> .
Adding a new target to an existing link	New <b>Target</b> in the <b>TargetsList</b> of the <b>NamespaceElement</b> and an update to the <b>TargetCount</b> .

The server MUST update the following fields in the DFS metadata for a domainv1-based DFS namespace.

Operation	DFS metadata changes required
Adding a new link	New <a href="#">DFSNamespaceLinkBLOB</a> and <b>BLOBElementCount</b> .
Adding a new target to an existing link	New <a href="#">TargetEntryBLOB</a> and updated <b>TargetCount</b> in existing <a href="#">DFSTargetListBLOB</a> , updated <b>DFSTargetListBLOBSize</b> and <b>BLOBDataSize</b> of <a href="#">DFSNamespaceLinkBLOB</a> .

The server MUST update the following fields in the DFS metadata for a domainv2-based DFS namespace.

Operation	DFS metadata changes required
Adding a new link	The following mandatory attributes MUST be updated: <b>msDFS-NamespaceIdentityGUIDv2</b> , <b>msDFS-LinkIdentityGUIDv2</b> , <b>msDFS-GenerationGUIDv2</b> , <b>msDFS-LinkPathv2</b> , <b>msDFS-LastModifiedv2</b> , <b>msDFS-TargetListv2</b> , <b>msDFS-Propertiesv2</b> , and <b>msDFS-Ttlv2</b> . The following optional attribute MAY be updated: <b>msDFS-Commentv2</b> . <a href="#">&lt;46&gt;</a>
Adding a new target to an existing link	Update <b>targetCount</b> , <b>totalStringLengthInBytes</b> , <b>priority</b> , and <b>state</b> attributes in <b>msDFS-TargetListv2</b> . Update <b>msDFS-LastModifiedv2</b> .

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetrDfsSetInfo \(Opnum 3\)](#) method with the Level parameter 101, and with the State field of [DFS INFO 101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE. <47><48>

### 3.1.4.1.4 NetrDfsRemove (Opnum 2)

The **NetrDfsRemove** method removes a link or a link target from a DFS namespace. A link can be removed regardless of the number of targets associated with it.

The **NetrDfsRemove** method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsRemove(
    [in, string] WCHAR* DfsEntryPath,
    [in, unique, string] WCHAR* ServerName,
    [in, unique, string] WCHAR* ShareName
);
```

**DfsEntryPath:** The pointer to the DFS link path that contains the name of an existing link.

**ServerName:** The pointer to a null-terminated Unicode DFS link target host name string. Clients MUST set *ServerName* to a NULL pointer in requests to remove the link and all its link targets.

**ShareName:** The pointer to a null-terminated Unicode DFS link target share name string. This may also be a share name with a path relative to the share, for example, "share1\mydir1\mydir2". Clients MUST set *ShareName* to a NULL pointer in requests to remove the link and all its link targets.

**Return Values:** This method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000002 ERROR_FILE_NOT_FOUND	The specified DFS link target was not found as a target of the specified DFS link.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000032 ERROR_NOT_SUPPORTED	The method does not support a domain-based namespace.
0x00000490 ERROR_NOT_FOUND	The specified DFS namespace or DFS link does not exist.

The **NetrDfsRemove** method SHOULD <49> support a domain-based DFS namespace. If it does not support a domain-based DFS namespace it MUST return ERROR\_NOT\_SUPPORTED.

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link *DfsEntryPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link target of the DFS link that the *ServerName* and *RootShare* parameters specify. If that existence check fails, the server MUST return ERROR\_FILE\_NOT\_FOUND.

If the *ServerName* and *ShareName* parameters are both NULL, the server MUST remove the link and all its link targets. If the *ServerName* and *ShareName* are not NULL, the server MUST remove the specified link target. If the specific target is the last target of the link, the server MUST remove the link as well. If only one of *ServerName* or *ShareName* is NULL, the server MUST return ERROR\_INVALID\_PARAMETER.

The server MUST synchronously update the following fields in the DFS metadata for a stand-alone DFS namespace.

Operation	DFS metadata changes required
Remove link	Remove corresponding <b>NamespaceElement</b> from <b>NamespaceElementsList</b> .
Remove link target	Remove <b>Target</b> from the <b>TargetsList</b> of the <b>NamespaceElement</b> , and update the <b>TargetCount</b> .

The server MUST update the following fields in the DFS metadata for a domainv1-based DFS namespace.

Operation	DFS metadata changes required
Remove link	Remove <a href="#">DFSNamespaceLinkBLOB</a> ; update BLOBElementCount.
Remove link target	Update TargetCount in existing DFSTargetListBLOB, remove <a href="#">TargetEntryBLOB</a> . Update DFSTargetListBLOBSize, update BLOBDataSize of DFSNamespaceLinkBLOB.

The server MUST update the following fields in the DFS metadata for a domainv2-based DFS namespace.

Operation	DFS metadata Changes Required
Remove link	Remove the DFS link object.
Remove link target	Update <b>TargetCount</b> and <b>totalStringLengthInBytes</b> attributes in msDFS-TargetListv2; update msDFS-LastModifiedv2.

A remove link operation in a domainv2-based DFS namespace first creates a dynamic object for the entry to be deleted. To create a dynamic object, the server MUST do the following:

- Set the object class to msDFS-DeletedLinkv2; a normal DFS link LDAP entry's object class is msDFS-Linkv2.
- Set the deleted DFS link's identity GUID.
- Set an updated msDFS-LastModifiedv2 time-stamp attribute.

If the dynamic object is created successfully, the original link LDAP entry is then deleted. If the delete is successful, the dynamic object is left intact; otherwise, the dynamic object is itself deleted. The advantage of using a dynamic object is that directory services perform garbage collection.

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetrDfsSetInfo](#) method with the *Level* parameter 101, and with the **State** field of [DFS INFO 101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE.<50><51>

### 3.1.4.1.5 NetrDfsSetInfo (Opnum 3)

The **NetrDfsSetInfo** method sets or modifies information relevant to a specific DFS root, DFS root target, DFS link, or DFS link target.

The **NetrDfsSetInfo** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsSetInfo(
    [in, string] WCHAR* DfsEntryPath,
    [in, unique, string] WCHAR* ServerName,
    [in, unique, string] WCHAR* ShareName,
    [in] DWORD Level,
    [in, switch_is(Level)] DFS_INFO_STRUCT* DfsInfo
);
```

**DfsEntryPath:** The pointer to a DFS root or a DFS link path.

**ServerName:** The pointer to a null-terminated Unicode DFS root target or DFS link target host name string. Clients MUST set this to a NULL pointer when the DFS root or DFS link is used and not the DFS root target or DFS link target.

**ShareName:** The pointer to a null-terminated Unicode string DFS root target or DFS link target host name. Clients MUST set this to a NULL pointer when the DFS root or DFS link is used and not the DFS root target or DFS link target.

**Level:** Specifies the information level of the data and, in turn, determines the action the method performs.

Value	Meaning
Level_100 0x00000064	Sets the comment associated with the root or link specified in the <i>DfsInfo</i> parameter. The <i>ServerName</i> and <i>ShareName</i> parameters MUST be NULL.
Level_101 0x00000065	Sets the state associated with the root, link, root target, or link target specified in <i>DfsInfo</i> .<52>
Level_102 0x00000066	Sets the time-out value associated with the root or link specified in <i>DfsInfo</i> . The <i>ServerName</i> and <i>ShareName</i> parameters MUST be ignored.
Level_103 0x00000067	Sets the property flags for the root or link specified in <i>DfsInfo</i> . The <i>ServerName</i> and <i>ShareName</i> parameters MUST be NULL.
Level_104 0x00000068	Sets the target priority rank and class for the root target or link target specified in <i>DfsInfo</i> .

Value	Meaning
Level_105 0x00000069	Sets the comment, state, time-out information, and property flags for the namespace root or link specified in <i>DfsInfo</i> . Does not apply to a root target or link target. The <i>ServerName</i> and <i>ShareName</i> parameters MUST be NULL.
Level_106 0x0000006A	Sets the target state and priority for the DFS root target or DFS link target specified in <i>DfsInfo</i> .<53> This does not apply to the DFS namespace root or link.
Level_107 0x0000006B	Sets the comment, state, time-out, security descriptor information, and property flags for the namespace root or link specified in <i>DfsInfo</i> . Does not apply to a root target or link target. The <i>ServerName</i> and <i>ShareName</i> parameters MUST be NULL. The security descriptor MUST NOT have owner, group, or <b>SACLs</b> in it.  The security descriptor MUST be a NULL, zero length value if used on a namespace root. In this case, note that it is equivalent to using Level_105.
Level_150 0x00000096	Sets the security descriptor associated with a DFS link. Only stand-alone DFS namespaces and domainv2-based DFS namespaces are supported. The <i>ServerName</i> and <i>ShareName</i> parameters MUST both be NULL. The security descriptor MUST NOT have owner, group, or SACLs in it.

The server MUST support Level values 100 and 101. The server SHOULD support Level values 102-107 and 150. If the server does not support the provided Level, it MUST fail the call.<54> The server SHOULD return error code ERROR\_INVALID\_PARAMETER for unsupported level values.<55>

**DfsInfo:** The pointer to a **DFS\_INFO\_STRUCT** union that contains the specified data. The value of the *Level* parameter selects the case of the union.

**Return Values:** This method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [MS-ERREF], section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000002 ERROR_FILE_NOT_FOUND	The specified DFS link target was not found as a target of the specified DFS link.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000032 ERROR_NOT_SUPPORTED	The specified operation is not supported.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS root namespace or DFS link, or DFS link or root target, does not exist.

The **NetrDfsSetInfo** method SHOULD<56> support a domain-based DFS namespace. If it does not support a domain-based DFS namespace it MUST return ERROR\_NOT\_SUPPORTED.

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link that the *DfsEntryPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link target of the DFS link that the *ServerName* and *RootShare* parameters specify. If that existence check fails, the server MUST return ERROR\_FILE\_NOT\_FOUND.

The server MUST fail any attempt to set the state of a DFS root, a DFS link, a DFS root target or a DFS link target to a value that is not specified for the *Level* parameter. The server MUST fail any attempt to set the property flags on a DFS link that are defined only for a DFS root.

When the *Level* parameter is 101 and the **State** field in the [DFS\\_INFO\\_101](#) structure is DFS\_VOLUME\_STATE\_RESYNCHRONIZE, the server MUST reload the contents of the DFSMetadataCache for the DFS namespace that the *ShareName* parameter specifies. It MUST then update its local DFS namespace information by comparing this information against the DFS metadata. The details of this update operation are implementation-dependent.

When level 107 is used for a DFS namespace root or for a domainv1-based DFS link, the *pSecurityDescriptor* parameter has no meaning because security descriptors cannot be associated with those objects. In these cases, if *pSecurityDescriptor* is not NULL, the server MUST fail with ERROR\_NOT\_SUPPORTED.

For domainv1-based DFS root, if the **Level** in the **DfsInfo** structure is 103, 105, or 107, and if the **PropertyFlagMask** field has the DFS\_PROPERTY\_FLAG\_ABDE flag set, the server MUST fail the call with ERROR\_NOT\_SUPPORTED.

If the **Level** in the **DfsInfo** structure is 103, 105, or 107, and if **PropertyFlagMask** field has DFS\_PROPERTY\_FLAG\_CLUSTER\_ENABLED flag set, the server MUST fail the call with ERROR\_NOT\_SUPPORTED.

The server MUST synchronously update the following fields in the DFS metadata for a stand-alone DFS namespace, depending on the value of the *Level* parameter.

Value	DFS metadata changes required
100 (0x00000064)	Update <b>Comment</b> in the <b>NamespaceElement</b> .
101 (0x00000065)	If a link, update the <b>State</b> field of <b>NamespaceElement</b> . If a root target or link target, update the <b>TargetState</b> field of <b>Target</b> .
102 (0x00000066)	Update the <b>ReferralTTL</b> field of <b>NamespaceElement</b> .
103 (0x00000067)	Update the <b>Properties</b> field of <b>NamespaceElement</b> .
104 (0x00000068)	Update the <b>PriorityRank</b> and <b>PriorityClass</b> fields of <b>Target</b> .
105 (0x00000069)	Update the <b>Comment</b> , <b>State</b> , <b>ReferralTTL</b> , and <b>Properties</b> fields of <b>NamespaceElement</b> .

Value	DFS metadata changes required
106 (0x0000006A)	Update the <b>PriorityRank</b> , <b>PriorityClass</b> , and <b>TargetState</b> fields of <b>Target</b> .
107 (0x0000006B)	Update the <b>Comment</b> , <b>State</b> , <b>ReferralTTL</b> , <b>SecurityDescriptor</b> , and <b>Properties</b> fields of <b>NamespaceElement</b> .
150 (0x00000096)	Update <b>SecurityDescriptor</b> of the <b>NamespaceElement</b> .

The server MUST update the following fields in the DFS metadata for a domainv1-based DFS namespace, depending on the value of the *Level* parameter.

Value	DFS metadata changes required
100 (0x00000064)	Update <b>CommentSize</b> and <b>Comment</b> in <a href="#">DFSRootOrLinkIDBLOB</a> and BLOBDataSize of <a href="#">DFSNamespaceLinkBLOB</a> .
101 (0x00000065)	If a link, update the <b>State</b> field of DFSRootOrLinkIDBLOB. If a root target or link target, update the <b>TargetState</b> field of <a href="#">TargetEntryBLOB</a> .
102 (0x00000066)	Update the <b>ReferralTTL</b> field of DFSNamespaceRootBLOB or DFSNamespaceLinkBLOB.
103 (0x00000067)	Update the <b>Type</b> field of DFSRootOrLinkIDBLOB.
104 (0x00000068)	Update the <b>PriorityRank</b> and <b>PriorityClass</b> fields of TargetEntryBLOB.
105 (0x00000069)	Update <b>CommentSize</b> and <b>Comment</b> in DFSRootOrLinkIDBLOB, the <b>State</b> field of DFSRootOrLinkIDBLOB, the <b>ReferralTTL</b> field of DFSNamespaceRootBLOB or DFSNamespaceLinkBLOB, and the <b>Type</b> field of DFSRootOrLinkIDBLOB.
106 (0x0000006A)	Update the <b>PriorityRank</b> , <b>PriorityClass</b> , and <b>TargetState</b> fields of TargetEntryBLOB.
107 (0x0000006B)	See 105 (0x00000069).

If the server does not support levels 104 or 106, it MUST use the [FILETIME](#) encoding for the **TargetTimestamp** field of the TargetEntryBLOB and update the field for each modified TargetEntryBLOB, as specified in section [2.3.3.1.1.3.1](#).

If the server supports levels 104 and 106, it MUST instead use the encoding which provides the **PriorityRank** and **PriorityClass** in the **TargetTimestamp** field.

Note that for interoperability, all root targets of a namespace SHOULD use the same encoding for this **TargetTimestamp** field.

The server MUST update the following fields in the DFS metadata for a domainv2-based DFS namespace, depending on the value of the *Level* parameter. For information about these fields, see section [2.3.4](#).

Value	DFS metadata changes required
100 (0x00000064)	Update msDFS-Commentv2.
101 (0x00000065)	<b>State</b> field of msDFS-TargetListv2.
102 (0x00000066)	Update msDFS-Ttlv2.
103 (0x00000067)	Update msDFS-Propertiesv2.
104 (0x00000068)	Update the <b>priorityClass</b> and <b>priorityRank</b> attributes in msDFS-TargetListv2.
105 (0x00000069)	Update msDFS-Commentv2, msDFS-Ttlv2, msDFS-Propertiesv2, and the State field of msDFS-Targetlistv2.
106 (0x0000006A)	Update priorityClass, priorityRank, and the State field of msDFS-TargetListv2.
107 (0x0000006B)	Update msDFS-Commentv2, msDFS-Ttlv2, msDFS-Propertiesv2, msDFS-LinkSecurityDescriptorv2, and the State field of msDFS-TargetListv2.
150 (0x00000096)	Update msDFS-LinkSecurityDescriptorv2.

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

For domainv2-based or standalone DFS root, if the DFS\_PROPERTY\_FLAG\_ABDE flag in **NamespaceElement.Properties** is either set or cleared as a result of this method, the server MUST communicate with the local SMB service to enable (DFS\_PROPERTY\_FLAG\_ABDE set) or disable (DFS\_PROPERTY\_FLAG\_ABDE cleared) the Access-Based Directory Enumeration property on the DFS root target by calling the **NetrShareSetInfo** method using Level 1005 (as specified in [\[MS-SRVS\]](#) section 3.1.4.11).

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST notify other DFS root targets of the change in DFS metadata by asynchronously issuing a **NetrDfsSetInfo** method with the *Level* parameter 101, and with the **State** field of **DFS\_INFO\_101** set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE. [<57>](#)

### 3.1.4.1.6 NetrDfsGetInfo (Opnum 4)

The **NetrDfsGetInfo** method returns information about a DFS root or a DFS link of the specified DFS namespace.

The **NetrDfsGetInfo** method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsGetInfo(
    [in, string] WCHAR* DfsEntryPath,
    [in, unique, string] WCHAR* ServerName,
    [in, unique, string] WCHAR* ShareName,
    [in] DWORD Level,
    [out, switch_is(Level)] DFS_INFO_STRUCT* DfsInfo
);
```

**DfsEntryPath:** The pointer to a DFS root or a DFS link path.

**ServerName:** This parameter MUST be a NULL pointer for Level\_50 and MUST be ignored for other levels.

**ShareName:** This parameter MUST be a NULL pointer for Level\_50 and MUST be ignored for other levels.

**Level:** This parameter specifies the information level of the data and, in turn, determines the action the method performs.

Value	Meaning
Level_1 0x00000001	Returns the name of the DFS root or the DFS link.
Level_2 0x00000002	Returns the name, comment, state, and number of targets for the DFS root or the DFS link.
Level_3 0x00000003	Returns the name, comment, state, number of targets, and target information for the DFS root or the DFS link.
Level_4 0x00000004	Returns the name, comment, state, time-out, GUID, number of targets, and target information for the DFS root or the DFS link.
Level_5 0x00000005	Returns the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets for the DFS root or the DFS link.
Level_6 0x00000006	Returns the name, comment, state, GUID, time-out, property flags, metadata size, number of targets, and target information for the DFS root or the DFS link.
Level_7 0x00000007	Returns the version number GUID of the DFS metadata. This value only applies to the DFS root.
Level_8 0x00000008	Returns the name, comment, state, time-out, GUID, property flags, metadata size, number of targets, and security descriptor associated with the DFS root or the DFS link.  Only stand-alone DFS namespaces and domainv2-based DFS namespaces are supported.
Level_9 0x00000009	Returns the name, comment, state, GUID, time-out, property flags, metadata size, number of targets, list of targets, and security descriptor for the DFS root or the DFS link.  Only stand-alone DFS namespaces and domainv2-based DFS namespaces are supported.
Level_50 0x00000032	Returns the DFS metadata version and capability information of an existing DFS namespace. This level is valid only for the DFS namespace root, not for DFS links. The <i>ServerName</i> and <i>ShareName</i> parameters MUST both be NULL. <a href="#">&lt;58&gt;</a>
Level_100 0x00000064	Returns the comment associated with the root or DFS link specified in the <i>DfsEntryPath</i> parameter.
Level_150 0x00000096	Returns the security descriptor associated with a DFS link.  Only stand-alone DFS namespaces and domainv2-based DFS namespaces are supported.

The server MUST support Level values 1-3 and 100. The server SHOULD support Level values 4-9, 50 and 150. If the server does not support the provided Level, it MUST fail the call. <59> The server SHOULD return error code ERROR\_INVALID\_PARAMETER for unsupported Level values. <60>

**DfsInfo:** The pointer to a [DFS\\_INFO\\_STRUCT](#) union to receive the returned information. The case of the union is selected by the value of the *Level* parameter.

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000032 ERROR_NOT_SUPPORTED	The specified operation is not supported.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS root or DFS link, or DFS link or root target does not exist.

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link that the *DfsEntryPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

For a standalone DFS namespace, the server MUST identify a consistent **GUID** for the specified DFS link or DFS root path. This value MUST conform to the expectations of **UUID** uniqueness provided by [\[RFC4122\]](#) or [\[C706\]](#), though those specific algorithms are not required. This GUID value MUST be used when responding to calls specifying a *Level* parameter whose corresponding return structure provides the GUID: values of 4, 5, 6, 8, or 9.

The server MUST use the following fields in the DFS metadata for a stand-alone DFS namespace to return the required information, depending on the value of the *Level* parameter.

Value	DFS metadata field
1 (0x00000001)	The <b>Prefix</b> field of <b>NamespaceElement</b> .
2 (0x00000002)	In addition to those for Level 1: the <b>Comment</b> and <b>State</b> fields of <b>NamespaceElement</b> and the <b>TargetCount</b> field of <b>TargetsList</b> .
3 (0x00000003)	In addition to those for Level 2: <b>Target</b> entries in the <b>TargetsList</b> .
4 (0x00000004)	In addition to those for Level 3: the <b>ReferralTTL</b> and <b>IdentityGUID</b> fields of <b>NamespaceElement</b> .
5	In addition to those for Level 4: the <b>Properties</b> field of <b>NamespaceElement</b> , and the

Value	DFS metadata field
(0x00000005)	size of the DFS namespace metadata, <61> but excluding <b>Target</b> entries.
6 (0x00000006)	In addition to those for Level 5: <b>Target</b> entries in the <b>TargetsList</b> .
7 (0x00000007)	The value of <b>GenerationGUID</b> attribute of the <b>Namespace</b> object.
8 (0x00000008)	In addition to those for Level 5: <b>SecurityDescriptor</b> of the <b>NamespaceElement</b> .
9 (0x00000009)	In addition to those for Level 6: <b>SecurityDescriptor</b> of the <b>NamespaceElement</b> .
50 (0x00000032)	No metadata attribute stores this data. The value returned MUST, however, be one of the values defined in the table in section <a href="#">2.2.3.10</a> .
100 (0x00000064)	<b>Comment</b> in <b>NamespaceElement</b> .
150 (0x00000096)	<b>SecurityDescriptor</b> of the <b>NamespaceElement</b> .

The server MUST use the following fields in the DFS metadata for a domainv1-based DFS namespace to return the required information, depending on the value of the *Level* parameter.

Value	DFS metadata field
1 (0x00000001)	The <b>PrefixSize</b> and <b>Prefix</b> fields of <a href="#">DFSRootOrLinkIDBLOB</a> .
2 (0x00000002)	In addition to those for Level 1: the <b>CommentSize</b> , <b>Comment</b> , and <b>State</b> fields of <a href="#">DFSRootOrLinkIDBLOB</a> and the <b>TargetCount</b> field of <a href="#">DFSTargetListBLOB</a> .
3 (0x00000003)	In addition to those for Level 2: <a href="#">TargetEntryBLOB</a> .
4 (0x00000004)	In addition to those for Level 3: the <b>ReferralTTL</b> field of <a href="#">DFSNamespaceRootBLOB</a> or <a href="#">DFSNamespaceLinkBLOB</a> ; the <b>RootOrLinkGuid</b> field of <a href="#">DFSRootOrLinkIDBLOB</a> .
5 (0x00000005)	In addition to those for Level 4: the <b>RootOrLinkGuid</b> field of <a href="#">DFSRootOrLinkIDBLOB</a> , the <b>Type</b> field of <a href="#">DFSRootOrLinkIDBLOB</a> , and the <b>Size</b> field of the value stored in the <b>pKT</b> attribute of the DFS namespace's object, but excluding <a href="#">TargetEntryBLOB</a> .
6 (0x00000006)	In addition to those for Level 5: <a href="#">TargetEntryBLOB</a> .
7 (0x00000007)	The Value of <b>pKTGuid</b> attribute of the DFS namespace's object.
50 (0x00000032)	No metadata attribute stores this data. The value returned MUST, however, be one of the values defined in the table in section <a href="#">2.2.3.10</a> .

Value	DFS metadata field
100 (0x00000064)	<b>CommentSize</b> and <b>Comment</b> in DFSRootOrLinkIDBLOB, and BLOBDataSize of DFSNamespaceLinkBLOB.

Note that for interoperability, all root targets of a namespace SHOULD use the same encoding for this **TargetTimestamp** field, as specified in section [2.3.3.1.1.3.1](#).

The server MUST use the following fields in the DFS metadata for a domainv2-based DFS namespace to return the required information, depending on the value of the *Level* parameter.

Value	DFS metadata field
1 (0x00000001)	The <b>msDFS-LinkPathv2</b> attribute.
2 (0x00000002)	In addition to those for Level 1: msDFS-Commentv2, msDFS-Propertiesv2, and the <b>TargetCount</b> field of msDFS-TargetListv2.
3 (0x00000003)	In addition to those for Level 2: <b>msDFS-TargetListv2</b> .
4 (0x00000004)	In addition to those for Level 3: msDFS-Ttlv2, msDFS-NamespaceIdentityGUIDv2 for DFS root, and msDFS-LinkIdentityGUIDv2 for DFS link.
5 (0x00000005)	In addition to those for Level 4: msDFS-Propertiesv2. Excludes msDFS-TargetListv2.
6 (0x00000006)	In addition to those for Level 4: msDFS-Propertiesv2.
7 (0x00000007)	The value of the <b>msDFS-GenerationGUIDv2</b> attribute of the DFS namespace's object.
8 (0x00000008)	In addition to those for Level 5: msDFS-LinkSecurityDescriptorv2.
9 (0x00000009)	In addition to those for Level 6: msDFS-LinkSecurityDescriptorv2.
50 (0x00000032)	The <b>msDFS-SchemaMajorVersion</b> and <b>msDFS-SchemaMinorVersion</b> attributes.
100 (0x00000064)	The <b>msDFS-Commentv2</b> attribute.
150 (0x00000096)	The <b>msDFS-LinkSecurityDescriptorv2</b> attribute.

### 3.1.4.1.7 NetrDfsEnum (Opnum 5)

The **NetrDfsEnum** method enumerates the DFS root hosted on a server or the DFS links of the namespace hosted by a server. Depending on the information level, the targets of the root and links are also displayed.

The **NetrDfsEnum** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsEnum(
    [in] DWORD Level,
    [in] DWORD PrefMaxLen,
    [in, out, unique] DFS_INFO_ENUM_STRUCT* DfsEnum,
    [in, out, unique] DWORD* ResumeHandle
);
```

**Level:** This parameter specifies the information level of the data and, in turn, determines the action that the method performs. On successful return, the server **MUST** return an array of the corresponding structures in the buffer pointed to by *DfsEnum*.

Value	Meaning
Level_1 0x00000001	Gets the name of the DFS root and all links beneath it. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_1</a> structures.
Level_2 0x00000002	Gets the name, comment, state, and number of targets for the DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_2</a> structures.
Level_3 0x00000003	Gets the name, comment, state, number of targets, and target information for the DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_3</a> structures.
Level_4 0x00000004	Gets the name, comment, state, time-out, GUID, number of targets, and target information for the DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_4</a> structures.
Level_5 0x00000005	Gets the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets for a DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_5</a> structures.
Level_6 0x00000006	Gets the name, comment, state, time-out, GUID, property flags, metadata size, number of targets, and target information for a DFS root or DFS links. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_6</a> structures.
Level_8 0x00000008	Gets the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets for a DFS root and all DFS links under the root. Also returns the security descriptor associated with each of the DFS links. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_8</a> structures.
Level_9 0x00000009	Gets the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets, and target information for a DFS root and all DFS links under the root. Also returns the security descriptor associated with each of the DFS links. In this case, on successful return <b>DfsEnum</b> <b>MUST</b> point to an array of <a href="#">DFS_INFO_9</a> structures.

The server **MUST** support **Level** values 1, 2 and 3. The server **SHOULD** support Level values 5, 6, 8, 9, and 300. The server on a DC **SHOULD** support Level value 200. If the server does not support the provided **Level**, it **MUST** fail the call. [<62>](#) The server **SHOULD** return error code ERROR\_INVALID\_PARAMETER for unsupported Level values. [<63>](#)

**PrefMaxLen:** This parameter specifies restrictions on the number of elements returned. A value of 0xFFFFFFFF means there are no restrictions, in which case all entries **MUST** be returned. [<64>](#)

**DfsEnum:** A pointer to a **DFS\_INFO\_ENUM\_STRUCT** union to receive the returned information. The client SHOULD set the **Level** member to the same value as the method's *Level* parameter, and MUST set the **DfsInfoContainer** union member to a pointer to the corresponding container structure as specified in section 2.2.6. The client MUST initialize the container structure's **EntriesRead** member to zero and **Buffer** member to a NULL pointer. The value of the **Level** member determines the case of the union.

**ResumeHandle:** This parameter is used to continue an enumeration when more data is available than can be returned in a single invocation of this method.

- If this parameter is not a NULL pointer, and the method returns **ERROR\_SUCCESS**, this parameter receives an implementation-specific nonzero value that can be passed in subsequent calls to this method to continue the enumeration.
- If this parameter is a NULL pointer or points to a 0 value, it indicates that this is an initial enumeration request.
- If this parameter is not a NULL pointer and points to a nonzero value returned in *ResumeHandle* by an earlier invocation of this method, the server will attempt to continue a previous enumeration, but MAY produce incomplete or inconsistent results due to the possibility of concurrent updates to the DFS namespace. <65>

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [MS-ERREF] section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000103 ERROR_NO_MORE_ITEMS	There is no data to return.
0x00000490 ERROR_NOT_FOUND	The specified DFS root namespace does not exist.
0x000010DF ERROR_DEVICE_NOT_AVAILABLE	The server hosts more than one root.

A server MAY <66> implement this method.

The server MUST verify that it hosts a DFS namespace. If that check fails, the server MUST return **ERROR\_NOT\_FOUND**.

The server MUST return **ERROR\_NO\_MORE\_ITEMS** (0x00000103) if there is no data to return.

The server MUST return **ERROR\_DEVICE\_NOT\_AVAILABLE** if the server hosts more than one root.

Each member of the **DFS\_INFO\_ENUM\_STRUCT** return buffer MUST be constructed according to the rules of section 3.1.4.1.6 (NetrDfsGetInfo) for the specified value of the *Level* parameter. <67>

If the requested *Level* is 1 through 9 and *ResumeHandle* indicates initial enumeration, the server MUST return the DFS root entry as the first member of the DFS\_INFO\_ENUM\_STRUCT return buffer followed by DFS links in implementation-specific order.

If the requested *Level* is 1 through 9 and *ResumeHandle* does not indicate initial enumeration, the server MUST NOT return the DFS root entry and all the entries of the DFS\_INFO\_ENUM\_STRUCT return buffer MUST be DFS links in implementation-specific order.

### 3.1.4.1.8 NetrDfsMove (Opnum 6)

The **NetrDfsMove (Opnum 6)** method renames or moves a DFS link. This method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsMove(
    [in, string] WCHAR* DfsEntryPath,
    [in, string] WCHAR* NewDfsEntryPath,
    [in] unsigned long Flags
);
```

**DfsEntryPath:** The pointer to a DFS path, this parameter specifies the source path for the move operation. This MUST be a DFS link or the path prefix of any DFS link in the DFS namespace.

**NewDfsEntryPath:** The pointer to a DFS path, this parameter specifies the destination DFS path for the move operation. This MUST be a path or a DFS link in the same DFS namespace.

**Flags:** A bit field specifying additional actions to take.

Value	Meaning
DFS_MOVE_FLAG_REPLACE_IF_EXISTS 0x00000001	If the destination path is an existing link, replace it as part of the move operation.

All other bits are reserved and MUST NOT be used. If reserved bits are specified, the server SHOULD fail the call with ERROR\_INVALID\_PARAMETER (0x00000057) .

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000032 ERROR_NOT_SUPPORTED	The specified operation is not supported.
0x00000050 ERROR_FILE_EXISTS	The destination path specifies an existing link.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.

Return value/code	Description
0x00000490 ERROR_NOT_FOUND	A specified DFS root namespace does not exist, or no links were matched.

The server MUST verify the existence of the DFS namespaces that the *DfsEntryPath* and *NewDfsEntryPath* parameters specify. If the existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST validate that the source and destination paths are

1. In the same DFS namespace.
2. Below the root of the namespace.

Otherwise, the server MUST return ERROR\_NOT\_SUPPORTED.

The server MUST return ERROR\_NOT\_FOUND if the *DfsEntryPath* parameter does not match any DFS links in the namespace, as specified below.

The server MUST validate that the source and destination paths do not specify illegal characters or path elements. If either path is illegal, the server MUST return ERROR\_INVALID\_NAME. <68>

The server SHOULD perform DFS link move operations atomically. That is, either all of the constituent operations are performed as part of the move and the call succeeds, or no changes are made to the DFS namespace and the call fails. <69>

When the source and destination are both paths in the DFS namespace and not links themselves, all DFS links in the DFS namespace that have the source path as their prefix MUST be converted to DFS links with the destination path as the prefix. In effect, each DFS link that has the prefix specified by the source path is removed, and new DFS links that have exactly the same targets and target properties are added, but with the prefix specified by the destination path. For example, with a source path of "\\MyServer\MyDfs\dir1" and a destination path of "\\MyServer\MyDfs\dir2", the DFS link "\\MyServer\MyDfs\dir1\link1" becomes "\\MyServer\MyDfs\dir2\link1", while the DFS link "\\MyServer\MyDfs\link2" is unaffected by the move operation.

If a DFS link already exists at the destination path, unless the *Flags* parameter is DFS\_MOVE\_FLAG\_REPLACE\_IF\_EXISTS, the server MUST fail the call with ERROR\_FILE\_EXISTS. This MUST be enforced only if the destination is an existing link, not if the destination is an existing file or directory. In the preceding example, if a DFS link "\\MyServer\MyDfs\dir2\link1" already exists, the move operation will fail unless the DFS\_MOVE\_FLAG\_REPLACE\_IF\_EXISTS flags parameter is specified. If the DFS\_MOVE\_FLAG\_REPLACE\_IF\_EXISTS flags parameter is specified, the DFS link at the destination path is removed and replaced by the moved DFS link. If "\\MyServer\MyDfs\dir2\link1" is an existing directory and not a link, the operation does not require the DFS\_MOVE\_FLAG\_REPLACE\_IF\_EXISTS flags parameter to be specified.

DFS servers SHOULD support the case in which intermediate or leaf pathname components in the destination path are files. For example, a server should support the case of a source path being "\\MyServer\MyDfs\dir1\link1", a destination path being "\\MyServer\MyDfs\comp1\link1", and "\\MyServer\MyDfs\comp1" being a file. <70>

If intermediate directories in the pathname of a source DFS link are empty, they SHOULD be removed, as required, after a move operation. For example, if "\\MyServer\MyDfs\dir1\dir2\link1" is moved to "\\MyServer\MyDfs\link1", the dir1 and dir2 directories are removed if they are empty. <71>

If the move operation results in a source DFS link becoming the prefix of an existing destination DFS link, the move operation MUST be failed. For example, if the source is a DFS link "\\MyServer\MyDfs\dir1\link1", the destination DFS link specified is "\\MyServer\MyDfs\dir2", and if a DFS link "\\MyServer\MyDfs\dir2\link2" already exists, the server MUST fail the call with ERROR\_FILE\_EXISTS.

For a domainv1-based DFS namespace and stand-alone DFS namespaces, the link's identity is changed. Thus, to another DFS root target of the same domainv1-based DFS namespace, one link is deleted and then another link is created instead of an existing link being moved.

The server MUST synchronously update the following fields in the DFS metadata for a stand-alone DFS namespace.

Operation	DFS metadata changes required
Remove link	Remove <b>NamespaceElement</b> from <b>NamespaceElementsList</b> .
Add link	Add <b>NamespaceElement</b> in <b>NamespaceElementsList</b> .

The server MUST update the following fields in the DFS metadata for a domainv1-based DFS namespace.

Operation	DFS metadata changes required
Remove link	Remove <a href="#">DFSNamespaceLinkBLOB</a> and update BLOBElementCount.
Add link	Add DFSNamespaceLinkBLOB and update BLOBElementCount.

In contrast, for a domainv2-based DFS namespace, the link's identity is not changed. Instead, the **msDFS-LinkPathv2**, **msDFS-LastModifiedv2**, and **msDFS-GenerationGUIDv2** attributes of a DFS link's LDAP entry are updated during a move operation. When a destination link is deleted, the required local state changes (on-disk, in-memory) are performed on the DFS root target server performing the move operation as well.

The server MUST update the following fields in the DFS metadata for a domainv2-based DFS namespace.

Operation	DFS metadata changes required
Remove link	Update <b>msDFS-LinkPathv2</b> , <b>msDFS-LastModifiedv2</b> , and <b>msDFS-GenerationGUIDv2</b> .
Add link	Update <b>msDFS-LinkPathv2</b> , <b>msDFS-LastModifiedv2</b> , and <b>msDFS-GenerationGUIDv2</b> .

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetDfsSetInfo \(Opnum 3\)](#) method with the *Level* parameter 101 and with the **State** field of [DFS INFO 101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE.<72>

The move operation on a stand-alone DFS namespace or a domainv2-based DFS namespace also correctly applies to any security descriptor that is associated with the DFS link, to the new reparse point created after the move operation.

### 3.1.4.1.9 NetrDfsAddRootTarget (Opnum 23)

The **NetrDfsAddRootTarget** method is used to create a stand-alone DFS namespace, a domainv1-based DFS namespace, or a domainv2-based DFS namespace. <73>

The **NetrDfsAddRootTarget** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsAddRootTarget(  
    [in, unique, string] LPWSTR DfsPath,  
    [in, unique, string] LPWSTR TargetPath,  
    [in] ULONG MajorVersion,  
    [in, unique, string] LPWSTR Comment,  
    [in] BOOLEAN NewNamespace,  
    [in] ULONG Flags  
);
```

**DfsPath:** The pointer to a null-terminated Unicode string. This MUST be \\<domain>\<dfsname> for domain-based DFS or \\<server>\<share> for stand-alone DFS.

**TargetPath:** The pointer to a null-terminated Unicode string. This MUST be \\<server>\<share>[\<path>] for domain-based DFS or NULL for stand-alone DFS. The latter restriction is required to ensure that a typographic error in the domain name, while attempting to create a domain-based DFS, does not result in a stand-alone DFS namespace being created on the DFS root target server, if the first pathname component of the *DfsPath* parameter is used to detect whether a domain-based DFS namespace or stand-alone DFS namespace is being created. When *TargetPath* is not NULL, the <server> MUST be used as the host name of the new DFS root target in the metadata.

**MajorVersion:** The DFS metadata version to use to create the DFS namespace. When adding a DFS root target to an existing DFS namespace, *MajorVersion* MUST be either 0 or the major version number of the existing DFS namespace. Otherwise, the call MUST fail.

**Comment:** The pointer to a null-terminated Unicode string that contains a comment associated with this root or link. This string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality. The comment MUST be ignored when adding a target to an existing link.

**NewNamespace:** A Boolean value that, if TRUE, indicates a request to create a new root. If FALSE, this value indicates a request to add a new root target to an existing root.

**Flags:** This parameter MUST be zero for a domain-based DFS namespace and MUST be ignored for a stand-alone DFS namespace.

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.

Return value/code	Description
0x000000B7 ERROR_ALREADY_EXISTS	The specified namespace already exists on this server.
0x00000906 NERR_NetNameNotFound	The share that the TargetPath parameter specifies does not already exist.

The following table summarizes the various actions that the **NetrDfsAddRootTarget** method takes based on the parameter values.

pDfsPath parameter	pTargetPath parameter	MajorVersion parameter	Explanation
\\<domain>\<dfsname>	\\<server>\<share>	1	Creates a new domainv1-based DFS namespace or adds a new root target to an existing domainv1-based DFS namespace. If a DFS namespace already exists, the version specified MUST match the DFS namespace; otherwise, the call fails.
\\<domain>\<dfsname>	\\<server>\<share>	2	Creates a new domainv2-based DFS namespace or adds a new root target to an existing domainv2-based DFS namespace. If a DFS namespace already exists, the version specified MUST match the DFS namespace; otherwise, the call fails.
\\<domain>\<dfsname>	\\<server>\<share>	0	Adds a new root target to an existing domain-based DFS namespace or a domainv2-based DFS namespace. If a DFS namespace does not already exist, the call fails.
\\<server>\<share>	NULL	1	Creates a new stand-alone DFS namespace.

The following scheme is used to create a new domainv2-based DFS namespace:

- [NetrDfsGetSupportedNamespaceVersion](#) is called to determine an appropriate version number to pass to the NetrDfsAddRootTarget() method.
- The client-side method creates a DFS metadata, format-independent LDAP entry called the DFS namespace anchor. It contains only the DFS metadata major version number.
- Updates the **access control list (ACL)** on the object of the DFS namespace to permit read/write access by the DFS root target server.
- The client-side method then issues an RPC call to the DFS root target server.
- The DFS server creates a new DFS namespace LDAP entry with the DFS namespace anchor LDAP entry as its parent.

- All DFS links are created with the DFS namespace LDAP entry as the parent. For more information, see section [2.3.2](#).

This results in two LDAP entries in domainv2 corresponding to the single LDAP entry in domainv1.

If the domain-based DFS namespace already exists, and the *ServerName* and **RootShare** parameters are a root target, the server MUST fail with ERROR\_ALREADY\_EXISTS.

If the share that the *TargetPath* parameter specifies does not already exist, the RPC method MUST fail with NERR\_NetNameNotFound (0x00000906).

The server MUST synchronously update the following fields in the stand-alone DFS metadata.

Operation	DFS metadata changes required.
Adding a new namespace	Creates a new <b>Namespace</b> object for the namespace, and inserts the object into <b>NamespaceList</b> .

The server MUST update the following fields in the domainv1-based DFS metadata.

Operation	DFS metadata changes required
Adding a new namespace	Creates new DFS metadata.
Adding a new root target	Updates the TargetCount field of the DFSTargetListBLOB, creates a new TargetEntryBLOB, updates the DFSTargetListBLOBSize, updates the BLOBDataSize of the DFSNamespaceRootBLOB, and adds the DFSRootTarget to the remoteServerName attribute in the object.

The server MUST update the following fields in the domainv2-based DFS metadata.

Operation	DFS metadata changes required
Adding a new namespace	Creates new DFS namespace LDAP entry with the DFS namespace anchor LDAP as its parent.
Adding a new root target	Updates the msDFS-TargetListv2 attribute, which is stored as an XML document, by adding *server* into the list of root targets.

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetrDfsSetInfo \(Opnum 3\)](#) method with the Level parameter 101 and with the **State** field of [DFS INFO 101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE.

### 3.1.4.1.10 NetrDfsRemoveRootTarget (Opnum 24)

The **NetrDfsRemoveRootTarget (Opnum 24)** method is the unified DFS namespace deletion method. It deletes stand-alone DFS namespaces, domainv1-based DFS namespaces, or domainv2-based DFS namespaces based on parameters specified. [<74>](#)

The **NetrDfsRemoveRootTarget (Opnum 24)** method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsRemoveRootTarget (
```

```

[in, unique, string] LPWSTR pDfsPath,
[in, unique, string] LPWSTR pTargetPath,
[in] ULONG Flags
);

```

**pDfsPath:** The pointer to a null-terminated Unicode string. This MUST be \\<domain>\<dfsname> for domain-based DFS or \\<server>\<share> for stand-alone DFS.

**pTargetPath:** The pointer to a null-terminated Unicode string. This MUST be \\<server>\<share>[\<path>] for domain-based DFS or NULL for stand-alone DFS.

**Flags:** A bit field specifying the type of removal operation. For a standalone namespace, this bit-field parameter MUST be zero. For a domain-based DFS namespace, it can be zero or the following value. Zero indicates a normal removal operation.

Value	Meaning
DFS_FORCE_REMOVE 0x80000000	Specifying this flag for a domain-based DFS namespace removes the root target even if it is not accessible.

All other bits are reserved and MUST NOT be used. If reserved bits are specified, the server SHOULD fail the call with an implementation-dependent failure value. <75>

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [MS-ERREF] section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000002 ERROR_FILE_NOT_FOUND	The specified DFS root target was not found as a target of the specified DFS namespace.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS root namespace does not exist.

The server MUST verify the existence of the DFS namespace that the *pDfsPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS root target of the DFS namespace that the *pTargetPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_FILE\_NOT\_FOUND.

The server MUST support deleting a DFS namespace without first requiring removal of all the DFS links in it.

The client-side method is responsible for deleting the DFS namespace anchor LDAP entry corresponding to a domainv2-based DFS namespace.

The server MAY support DFS\_FORCE\_REMOVE on **member servers**.<76> If it is not supported and DFS\_FORCE\_REMOVE is specified, the server MUST return a failure.

If DFS\_FORCE\_REMOVE is not specified and it is a domain-based DFS namespace, the server MUST verify it is the host specified by the *pTargetPath* parameter. If it is not, the server MUST return ERROR\_FILE\_NOT\_FOUND.

If DFS\_FORCE\_REMOVE is not specified, the server SHOULD<77> also remove any local information related to hosting the removed root target. If DFS\_FORCE\_REMOVE is specified, the server MUST NOT do so.

The effect of DFS\_FORCE\_REMOVE is to clean up after the named root target has become nonfunctional and is unable to remove itself from the namespace.

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

The server SHOULD remove any intermediate directories and reparse points that were part of the namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetDfsSetInfo \(Opnum 3\)](#) method with the Level parameter 101 and with the **State** field of [DFS\\_INFO 101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE.

The following table summarizes the various actions that the **NetDfsRemoveRootTarget** method takes based on the parameter values.

<b>pDfsPath parameter</b>	<b>pTargetPath parameter</b>	<b>Explanation</b>
\\<domain>\<dfsname>	\\<server>\<share>	Deletes a domain-based DFS root target. If the DFS root target that is removed is the last one for the DFS namespace, then it removes the DFS namespace itself. This parameter can be used for either a domainv1-based DFS namespace or a domainv2-based DFS namespace.
\\<server>\<dfsname>	NULL	Deletes a stand-alone DFS namespace.

### 3.1.4.1.11 NetDfsGetSupportedNamespaceVersion (Opnum 25)

The **NetDfsGetSupportedNamespaceVersion (Opnum 25)** method is used to determine the supported DFS metadata version number.<78>

The **NetDfsGetSupportedNamespaceVersion (Opnum 25)** method has the following MIDL syntax.

```
NET_API_STATUS NetDfsGetSupportedNamespaceVersion(  
    [in] DFS_NAMESPACE_VERSION_ORIGIN Origin,  
    [in, unique, string] NETDFS_SERVER_OR_DOMAIN_HANDLE pName,  
    [out] PDFS_SUPPORTED_NAMESPACE_VERSION_INFO pVersionInfo  
);
```

**Origin:** This parameter specifies the version information requested.

Value	Meaning
DFS_NAMESPACE_VERSION_ORIGIN_SERVER 0x0001	This specifies that the returned information MUST reflect the metadata versions supported by the server.  Versions supported by the server may be higher (or lower) than those supported by the domain.
DFS_NAMESPACE_VERSION_ORIGIN_DOMAIN 0x0002	This specifies that the returned information MUST reflect the metadata versions supported by the domain schema of the domain to which the server is joined.  Versions supported by the domain schema may be higher (or lower) than those supported by the server.

**pName:** The pointer to a null-terminated Unicode string. The server MUST ignore the *pName* parameter.

**pVersionInfo:** The pointer to a [DFS SUPPORTED NAMESPACE VERSION INFO](#) structure to receive the DFS metadata version number determined.

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.

The standalone namespace version supported by a server may be unaffected by the domain metadata schema. If this is the case, the server MUST return a standalone DFS major and minor version of zero for the DFS\_NAMESPACE\_VERSION\_ORIGIN\_DOMAIN query. In this case, the standalone DFS capability field has no meaning and MUST also be zero.

The version number of the DFS metadata that can be used for a new DFS namespace depends on the following:

- For domain-based DFS namespaces, the version supported by the DFS metadata schema in use in the server's domain.
- The version supported by the server that is to host the DFS root target.

Thus, the version that can be used for creating a new DFS namespace is the minimum version that the domain and the server support.

This method is useful in determining an appropriate version number to pass to the [NetrDfsAddRootTarget](#) method.

### 3.1.4.2 Extended Methods

#### 3.1.4.2.1 NetrDfsAdd2 (Opnum 19)

The **NetrDfsAdd2 (Opnum 19)** method creates a new DFS link or adds a new target to an existing link of a DFS namespace.

The **NetrDfsAdd2** method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsAdd2(  
    [in, string] WCHAR* DfsEntryPath,  
    [in, string] WCHAR* DcName,  
    [in, string] WCHAR* ServerName,  
    [in, unique, string] WCHAR* ShareName,  
    [in, unique, string] WCHAR* Comment,  
    [in] DWORD Flags,  
    [in, out, unique] DFSM_ROOT_LIST** ppRootList  
);
```

**DfsEntryPath:** A pointer to a DFS link path that contains the name of an existing link when additional link targets are added or the name of a new link is created.

**DcName:** A pointer to a null-terminated Unicode string. For a domain-based DFS namespace, this is the host name of the DC that the DFS root target uses to get or update DFS metadata for the DFS namespace. This parameter MAY be a NULL pointer; otherwise, it MUST be the host name of the PDC for the domain of the DFS namespace. <79>

**ServerName:** A pointer to a null-terminated Unicode string that specifies the DFS link target host name.

**ShareName:** A pointer to a null-terminated Unicode DFS link target share name string. This may also be a share name with a path relative to the share (for example, `share1\mydir1\mydir2`). When specified in this manner, each pathname component MUST be a directory.

**Comment:** A pointer to a null-terminated, human-readable Unicode string description associated with this root or link. This string is not subject to protocol-specified restrictions on length or content and does not affect server functionality. The description MUST be ignored when adding a target to an existing link.

**Flags:** The flag that indicates the operation to perform. The following table lists the possible values.

Value	Meaning
0x00000000	Create a new link or add a new target to an existing link.
DFS_ADD_VOLUME 0x00000001	Create a new link in the DFS namespace if one does not already exist or fail if it exists.
DFS_RESTORE_VOLUME 0x00000002	Add a target without verifying its existence.

If the *Flags* value is not a bitwise OR of the values above, the server MUST return `ERROR_INVALID_PARAMETER (0x00000057)`.

**ppRootList:** On success, returns a list of DFS root targets in the domain-based DFS namespace that the client will be responsible for notifying of the change in the DFS namespace. See section [3.2.4.2.1](#). This list MAY be empty if the server performs the notification. [<80>](#)

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	The operation completed successfully.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000050 ERROR_FILE_EXISTS	The specified DFS link target already exists.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS namespace does not exist.
0x00000906 NERR_NetNameNotFound	The DFS link target does not exist.

A server MAY [<81>](#) implement this method.

If the [NetrDfsAdd \(Opnum 1\)](#) method on a server does not support a domain-based namespace, the server SHOULD support a domain-based namespace in the **NetrDfsAdd2 (Opnum 19)** method. [<82><83>](#)

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify whether the link to be added overlaps an existing link. If there is a link for which the specified *DfsEntryPath* parameter is a prefix, the server MUST return ERROR\_FILE\_EXISTS.

If the link to be added already exists, and DFS\_ADD\_VOLUME is set in the **Flags** field of the request, the server MUST return ERROR\_FILE\_EXISTS.

If the link to be added already exists, and DFS\_ADD\_VOLUME is not set in the **Flags** field of the request, the server MUST attempt to add a new link target to the link. If a target with the path specified by *ServerName* and *ShareName* was already added to the link, the server MUST return ERROR\_FILE\_EXISTS.

If DFS\_RESTORE\_VOLUME is not specified on the Flags parameter, the server MAY [<84>](#) choose to verify whether the link target exists. If DFS\_RESTORE\_VOLUME is specified, the server MUST NOT perform this test. If it performs the test and the link target does not exist, the server MUST fail the call with NERR\_NetNameNotFound.

The exact test the server performs to verify link target existence is implementation-defined. A server MAY, [<85>](#) for example, be implemented with the expectation that all link targets are

administered through [\[MS-SRVS\]](#) section 3.1.4.10 and use NetShareGetInfo level 1005 to perform the test. Reasons not to implement this test include:

- It may not be practical to determine the correct administration interface to query to perform the test.
- A link target server may export a share with a network protocol and administration interface that this server does not understand.
- A secured link target server may not permit this server to contact it.

The *Comment* parameter MUST be ignored when adding a target to an existing link.

The server SHOULD [<86>](#) create a new link without requiring the *DFS\_ADD\_VOLUME Flags* parameter.

The server MUST update the same fields in the DFS metadata for a domain-based DFS namespace as in the **NetrDfsAdd** method, as specified in section [3.1.4.1.3](#).

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST do one of the following:

- Notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetrDfsSetInfo](#) method with the *Level* parameter 101 and with the **State** field of [DFS INFO 101](#) set to *DFS\_VOLUME\_STATE\_RESYNCHRONIZE*. The returned *ppRootList* parameter MUST be empty.
- Perform no notification of the other root targets, returning a list of DFS root targets to the client in the *ppRootList* parameter.

### 3.1.4.2.2 NetrDfsRemove2 (Opnum 20)

The **NetrDfsRemove2 (Opnum 20)** method removes the specified link or link target.

The **NetrDfsRemove2** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsRemove2(  
    [in, string] WCHAR* DfsEntryPath,  
    [in, string] WCHAR* DcName,  
    [in, unique, string] WCHAR* ServerName,  
    [in, unique, string] WCHAR* ShareName,  
    [in, out, unique] DFSM_ROOT_LIST** ppRootList  
);
```

**DfsEntryPath:** The pointer to a DFS link path that contains the name of the DFS link to remove.

**DcName:** The pointer to a null-terminated Unicode string. For a domain-based DFS namespace, this string contains the host name of the DC to be used by the DFS root target that is removing the DFS link. This parameter MAY be a NULL pointer; otherwise, it MUST be the PDC for the domain of the DFS namespace. [<87>](#)

**ServerName:** The pointer to a null-terminated Unicode DFS link target host name string. This MUST be a NULL pointer when the link and all of the link targets are to be removed.

**ShareName:** The pointer to a null-terminated Unicode DFS link target share name string. This MUST be a NULL pointer when the link and all of the link targets are to be removed.

**ppRootList:** On success, returns a list of DFS root targets in the domain-based DFS namespace that the client will be responsible for notifying of the change in the DFS namespace. See section [3.2.4.2.2](#). This list MAY be empty if the server has performed the notification. [<88>](#)

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000002 ERROR_FILE_NOT_FOUND	The specified DFS link target was not found as a target of the specified DFS link.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS namespace or DFS link does not exist.

The server MAY [<89>](#) implement this method.

If the [NetrDfsRemove \(Opnum 2\)](#) method on a server does not support a domain-based namespace, the server SHOULD support a domain-based namespace in the **NetrDfsRemove2 (Opnum 20)** method. [<90>](#) [<91>](#)

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link *DfsEntryPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link target of the DFS link that the *ServerName* and *RootShare* parameters specify. If that existence check fails, the server MUST return ERROR\_FILE\_NOT\_FOUND.

If the *ServerName* and *ShareName* parameters are both NULL, the server MUST remove the link and all its link targets. If the *ServerName* and *ShareName* are not NULL, the server MUST remove the specified link target. If the specific target is the last target of the link, the server MUST remove the link as well. If only one of *ServerName* or *ShareName* is NULL, the server MUST return ERROR\_INVALID\_PARAMETER.

The server MUST update the same fields in the DFS metadata for a domain-based DFS namespace, as specified in the **NetrDfsRemove** method.

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST do one of the following:

- Notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetrDfsSetInfo](#) method with the *Level* parameter 101, and with the **State** field of [DFS\\_INFO\\_101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE. The returned *ppRootList* parameter MUST be empty.
- Perform no notification of the other root targets, returning a list of DFS root targets to the client in the *ppRootList* parameter.

### 3.1.4.2.3 NetrDfsEnumEx (Opnum 21)

The **NetrDfsEnumEx (Opnum 21)** method enumerates the DFS roots hosted on a server, or DFS links of a namespace hosted by the server. [<92><93>](#) Depending on the information level, the targets associated with the roots and links are also displayed.

The **NetrDfsEnumEx** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsEnumEx(
    [in, string] WCHAR* DfsEntryPath,
    [in] DWORD Level,
    [in] DWORD PrefMaxLen,
    [in, out, unique] DFS_INFO_ENUM_STRUCT* DfsEnum,
    [in, out, unique] DWORD* ResumeHandle
);
```

**DfsEntryPath:** The pointer to a domain name, a host name, or a DFS path, depending on the *Level* parameter.

- A domain name MUST be a null-terminated Unicode string in the following forms:

<DomainName> or \<DomainName> or \\<DomainName>

where <DomainName> is the domain name to use for the enumeration.

- A host name MUST be a null-terminated Unicode string in the following formats:

<ServerName> or \<ServerName> or \\<ServerName>

where <ServerName> is a host name.

- A DFS root or a DFS link path.

When *DfsEntryPath* points to a DFS link path, the remaining path after the DFS namespace name MUST be ignored.

**Level:** This parameter specifies the information level of the data and in turn determines the action the method performs. On successful return, the server MUST return an array of the corresponding structures in the buffer pointed to by [DfsEnum](#).

Value	Meaning
Level_1	Gets the name of the DFS root and all links beneath it. In this case, on successful

Value	Meaning
0x00000001	return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 1</a> structures.
Level_2 0x00000002	Gets the name, comment, state, and number of targets for the DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 2</a> structures.
Level_3 0x00000003	Gets the name, comment, state, number of targets, and information about each target for the DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 3</a> structures.
Level_4 0x00000004	Gets the name, comment, state, time-out, GUID, number of targets, and information about each target for the DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 4</a> structures.
Level_5 0x00000005	Gets the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets for a DFS root and all links under the root. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 5</a> structures.
Level_6 0x00000006	Gets the name, comment, state, time-out, GUID, property flags, metadata size, number of targets, and target information for a root or link. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 6</a> structures.
Level_8 0x00000008	Gets the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets for a DFS root and all links under the root. Also returns the security descriptor associated with each of the DFS links. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 8</a> structures.
Level_9 0x00000009	Gets the name, comment, state, time-out, GUID, property flags, metadata size, and number of targets and target information for a DFS root and all links under the root. Also returns the security descriptor associated with each of the DFS links. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 9</a> structures.
Level_200 0x000000C8	Enumerates all of the domain-based DFS namespace in the specified domain. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 200</a> structures.
Level_300 0x0000012C	Enumerates the stand-alone and domain-based DFS roots that the server hosts. In this case, on successful return <b>DfsEnum</b> MUST point to an array of <a href="#">DFS INFO 300</a> structures.

The server MUST support Level values 1, 2 and 3. The server SHOULD support Level values 5, 6, 8, 9, and 300. The server on a DC SHOULD support Level value 200. [<94>](#) If the server does not support the provided Level, it MUST fail the call. The server SHOULD return error code ERROR\_INVALID\_PARAMETER for unsupported Level values. [<95>](#)

**PrefMaxLen:** This parameter specifies restrictions on the number of elements returned. A value of 0xFFFFFFFF means there are no restrictions, in which case all entries MUST be returned. [<96>](#)

**DfsEnum:** A pointer to a **DFS\_INFO\_ENUM\_STRUCT** union to receive the returned information. The client SHOULD set the **Level** member to the same value as the method's *Level* parameter, and MUST set the **DfsInfoContainer** union member to a pointer to the corresponding container structure as specified in section [2.2.6](#). The client MUST initialize the

container structure's **EntriesRead** member to zero and the **Buffer** member to a NULL pointer. The value of the **Level** member determines the case of the union.

**ResumeHandle:** This parameter is used to continue an enumeration when more data is available than can be returned in a single invocation of this method.

- If this parameter is not a NULL pointer, and the method returns `ERROR_SUCCESS`, this parameter receives an implementation-specific nonzero value that can be passed in subsequent calls to this method to continue the enumeration.
- If this parameter is a NULL pointer, or it points to a zero value, it indicates that this is an initial enumeration.
- If this parameter is not a NULL pointer, and it points to a nonzero value returned in *ResumeHandle* by an earlier invocation of this method, the server will attempt to continue a previous enumeration. <97>

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#), section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000103 ERROR_NO_MORE_ITEMS	There is no data to return.
0x00000490 ERROR_NOT_FOUND	The specified DFS root namespace does not exist.

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If that existence check fails, the server MUST return `ERROR_NOT_FOUND`.

The server MUST return `ERROR_NO_MORE_ITEMS` (0x00000103) if there is no data to return.

Unlike the [NetrDfsEnum](#) method, this method can be used even when the server is hosting more than one DFS root.

If the server hosts exactly one DFS namespace, the requested *Level* is 1 through 9, and the *DfsEntryPath* does not specify a DFS namespace name, the server MAY enumerate the namespace it hosts. <98>

Each member of the `DFS_INFO_ENUM_STRUCT` return buffer MUST be constructed according to the rules of section 3.1.4.1.6 ([NetrDfsGetInfo](#)) for the specified value of the *Level* parameter.

If the requested *Level* is 1 through 9 and *ResumeHandle* indicates initial enumeration, the server MUST return the DFS root entry as the first member of the `DFS_INFO_ENUM_STRUCT` return buffer followed by DFS links in implementation-specific order.

If the requested *Level* is 1 through 9 and *ResumeHandle* does not indicate initial enumeration, the server MUST NOT return the DFS root entry and all the entries of the `DFS_INFO_ENUM_STRUCT` return buffer MUST be DFS links in implementation-specific order.

### 3.1.4.2.4 NetrDfsSetInfo2 (Opnum 22)

The **NetrDfsSetInfo2 (Opnum 22)** method sets or modifies the information associated with a DFS root, a DFS root target, a DFS link, or a DFS link target.

The **NetrDfsSetInfo2** method has the following MIDL syntax.

```
NET_API_STATUS NetrDfsSetInfo2(  
    [in, string] WCHAR* DfsEntryPath,  
    [in, string] WCHAR* DcName,  
    [in, unique, string] WCHAR* ServerName,  
    [in, unique, string] WCHAR* ShareName,  
    [in] DWORD Level,  
    [in, switch_is(Level)] DFS_INFO_STRUCT* pDfsInfo,  
    [in, out, unique] DFSM_ROOT_LIST** ppRootList  
);
```

**DfsEntryPath:** The pointer to a DFS root path or a DFS link path that contains the name of a DFS root or DFS link name.

**DcName:** The pointer to a null-terminated Unicode string. It MUST be ignored for a stand-alone DFS namespace. For a domain-based DFS namespace, this string contains the host name of the DC that the DFS root target uses to get or update DFS metadata for the DFS namespace. This parameter MAY be a NULL pointer; otherwise, it MUST be the PDC for the domain of the DFS namespace. [<99>](#)

**ServerName:** The pointer to a null-terminated Unicode DFS root target or a DFS link target host name string. This parameter MUST be a NULL pointer if the operation is intended for a DFS root or a DFS link and not for targets.

**ShareName:** The pointer to a null-terminated Unicode DFS root target or a DFS link target share name string. This parameter MUST be a NULL pointer if the operation is intended for a DFS root or a DFS link and not for targets.

**Level:** This parameter specifies the information level of the data and, in turn, determines the action the method performs.

Value	Meaning
Level_100 0x00000064	Sets the comment associated with the root or link that specified in <i>DfsInfo</i> .
Level_101 0x00000065	Sets the storage state associated with the root, link, root target, or link target specified in <i>DfsInfo</i> . <a href="#">&lt;100&gt;</a>
Level_102 0x00000066	Sets the time-out value associated with the root or link specified in <i>DfsInfo</i> .
Level_103 0x00000067	Sets the property flags for the root or link specified in <i>DfsInfo</i> .
Level_104 0x00000068	Sets the target priority rank and class for the root target or link target specified in <i>DfsInfo</i> .
Level_105 0x00000069	Sets the comment, state, time-out information, and property flags for the root or link specified in <i>DfsInfo</i> . This does not apply to a root target or link target.

Value	Meaning
Level_106 0x0000006A	Sets the target state and priority for the root target or link target specified in <i>DfsInfo</i> . This does not apply to the DFS namespace root or link. <101>
Level_107 0x0000006B	Sets the comment, state, time-out, security descriptor information, and property flags for the root or link specified in <i>DfsInfo</i> . Does not apply to a root target or link target. The <i>ServerName</i> and <i>ShareName</i> parameters MUST be NULL. The security descriptor MUST NOT have an owner, group, or SACLs in it.  The security descriptor MUST be a NULL, zero length value if used on a namespace root. In this case, note that it is equivalent to using Level_105.
Level_150 0x00000096	Sets the security descriptor associated with a link. Only stand-alone DFS namespaces and domainv2-based DFS namespaces are supported. The <i>ServerName</i> and <i>ShareName</i> parameters MUST both be NULL. The security descriptor MUST NOT have an owner, group, or SACLs in it.

The server MUST support Level values 100 and 101. The server SHOULD support Level values 102-107 and 150. If the server does not support the provided Level, it MUST fail the call. <102> The server SHOULD return error code ERROR\_INVALID\_PARAMETER for unsupported Level values. <103>

**pDfsInfo:** The pointer to a [DFS\\_INFO\\_STRUCT](#) union that contains the specified data. The *Level* parameter value determines the case of the union.

**ppRootList:** On success, returns a list of DFS root targets in the domain-based DFS namespace which the client will be responsible for notifying about the change in the DFS namespace. See section [3.2.4.2.3](#). This list MAY be empty if the server has performed the notification. <104>

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000002 ERROR_FILE_NOT_FOUND	The specified DFS link target was not found as a target of the specified DFS link.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000032 ERROR_NOT_SUPPORTED	The specified operation is not supported.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x00000490 ERROR_NOT_FOUND	The specified DFS root, DFS link, or DFS link or root target does not exist.

The server MAY <105> implement this method.

If the [NetrDfsSetInfo \(Opnum 3\)](#) method on a server does not support a domain-based namespace, the server SHOULD support a domain-based namespace in the **NetrDfsSetInfo2 (Opnum 22)** method. [<106><107>](#)

The server MUST verify the existence of the DFS namespace that the *DfsEntryPath* parameter specifies. If the namespace does not exist, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link that the *DfsEntryPath* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS link target of the DFS link that the *ServerName* and *RootShare* parameters specify. If that existence check fails, the server MUST return ERROR\_FILE\_NOT\_FOUND.

If the *DcName* parameter is not NULL, it MUST be the PDC for the domain of the domain-based DFS namespace.

The server MUST fail any attempt to set the state of a DFS root, a DFS link, a DFS root target, or a DFS link target to a value that is not specified. The server MUST fail any attempt to set the property flags on a DFS link that are defined only for a DFS root.

With the *Level* parameter 101 and the **State** field in the [DFS\\_INFO\\_101](#) structure as DFS\_VOLUME\_STATE\_RESYNCHRONIZE, the server MUST reload the contents of the DFSMetadataCache, if maintained, for the domain-based DFS namespace that the *ShareName* parameter specifies. In the case of both domain-based DFS namespaces and stand-alone DFS namespaces, the server MUST check the DFS namespace it hosts locally with the DFS metadata and perform any required modifications.

With the *Level* parameter 101 and the **State** field in the **DFS\_INFO\_101** structure as DFS\_VOLUME\_STATE\_FORCE\_SYNC, the server MUST perform a full synchronization instead of an incremental synchronization to reload the contents of the DFSMetadataCache and to identify added or deleted DFS links. This **State** field is supported on domainv2-based DFS namespaces and stand-alone DFS namespaces.

When *level* parameter 107 is used for a DFS namespace root or for a domainv1-based DFS link, the *pSecurityDescriptor* parameter has no meaning because security descriptors cannot be associated with those objects. In these cases, if *pSecurityDescriptor* is not NULL, the server MUST fail with ERROR\_NOT\_SUPPORTED.

The server MUST update the same fields in the DFS metadata for a domain-basedv1 DFS namespace as for the **NetrDfsSetInfo (Opnum 3)** method, as specified in section [3.1.4.1.5](#).

The server MUST synchronously update the DFS metadata of a domain-based DFS namespace.

If DFS root scalability mode is not enabled for the domain-based DFS namespace, the server MUST do one of the following:

- Notify other DFS root targets of the change in DFS metadata by asynchronously issuing a **NetrDfsSetInfo (Opnum 3)** method with the *Level* parameter 101 and with the **State** field of [DFS\\_INFO\\_101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE. The returned *ppRootList* parameter MUST be empty.
- Perform no notification of the other root targets, returning a list of DFS root targets to the client in the *ppRootList* parameter.

### 3.1.4.3 Root Target Methods

#### 3.1.4.3.1 NetrDfsAddFtRoot (Opnum 10)

The **NetrDfsAddFtRoot (Opnum 10)** method creates a new domainv1-based DFS namespace or adds a root target to an existing namespace.

The **NetrDfsAddFtRoot** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsAddFtRoot(  
    [in, string] WCHAR* ServerName,  
    [in, string] WCHAR* DcName,  
    [in, string] WCHAR* RootShare,  
    [in, string] WCHAR* FtDfsName,  
    [in, string] WCHAR* Comment,  
    [in, string] WCHAR* ConfigDN,  
    [in] BOOLEAN NewFtDfs,  
    [in] DWORD ApiFlags,  
    [in, out, unique] DFSM_ROOT_LIST** ppRootList  
);
```

**ServerName:** The pointer to a null-terminated Unicode string. This MUST be used as the host name of the new DFS root target in the metadata. [<108>](#)

**DcName:** The pointer to a null-terminated Unicode string. For a domainv1-based DFS namespace, this string contains the host name of the DC that the new DFS root target is to use to get or update DFS metadata for the DFS namespace. This parameter MAY be a NULL pointer, otherwise, it MUST be the PDC for the domain of the DFS namespace.

**RootShare:** The pointer to a null-terminated Unicode string. This is the new DFS root target share name. This may be different from the *FtDfsName* parameter. The share MUST already exist.

**FtDfsName:** The pointer to a null-terminated Unicode string. This is the name of the new or existing domain-based DFS namespace.

**Comment:** The pointer to a null-terminated Unicode string that contains a comment associated with the DFS namespace. Used for informational purposes, this string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality. This parameter MAY be NULL.

**ConfigDN:** The pointer to a null-terminated Unicode string. This string MUST be the path of the DFS namespace object entry in the DFS Configuration Container (see section [2.3.3](#)). [<109>](#)

**NewFtDfs:** A Boolean value that, if TRUE, indicates a request to create a new root. If FALSE, then this value indicates a request to add a new root target to an existing root.

**ApiFlags:** This parameter MUST be 0.

**ppRootList:** On success, returns a list of DFS root targets in the domain-based DFS namespace that the client will be responsible for notifying of the change in the DFS namespace. See section [3.2.4.3.1](#). The list MAY be empty if the server has performed the notification. [<110>](#)

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.
0x000000B7 ERROR_ALREADY_EXISTS	A namespace of the specified name already exists on the server.
0x00000906 NERR_NetNameNotFound	The share that the <i>RootShare</i> parameter specifies does not already exist.

The share that the *RootShare* parameter specifies MUST already exist on the server.

If the *DcName* parameter is not NULL, the server assumes that this is the PDC for the domain in which the DFS namespace is to be created.

If the domain-based DFS namespace already exists, and the *ServerName* and *RootShare* parameters are a root target, the server MUST fail with ERROR\_ALREADY\_EXISTS.

If the share that the *RootShare* parameter specifies does not already exist, the RPC method MUST fail with NERR\_NetNameNotFound (0x00000906).

The server MUST update the following fields in the domainv1-based DFS metadata.

Operation	DFS metadata changes required
Adding a new namespace	Creates new DFS metadata.
Adding a new root target	Updates the <b>TargetCount</b> field of the <a href="#">DFSTargetListBLOB</a> , creates a new <a href="#">TargetEntryBLOB</a> , updates the DFSTargetListBLOBSize, updates the BLOBDataSize of the <a href="#">DFSNamespaceRootBLOB</a> , and adds the DFSRootTarget to the <b>remoteServerName</b> attribute in the object.

The server MUST synchronously update the DFS metadata.

The server MUST return a list of DFS root targets to the client in the *ppRootList* parameter. [<111>](#)

### 3.1.4.3.2 NetrDfsRemoveFtRoot (Opnum 11)

The **NetrDfsRemoveFtRoot (Opnum 11)** method removes the specified root target from a domainv1-based DFS namespace. [<112>](#) If the target is the last one associated with the DFS namespace, then this method also deletes the DFS namespace. The DFS namespace can be removed without first removing all of the links in it.

If a client tries to use this method on a domainv2-based DFS namespace target, then the server MUST fail with the return value of ERROR\_NOT\_SUPPORTED.

The **NetrDfsRemoveFtRoot** method uses the following MIDL syntax.

```

NET_API_STATUS NetrDfsRemoveFtRoot (
    [in, string] WCHAR* ServerName,
    [in, string] WCHAR* DcName,
    [in, string] WCHAR* RootShare,
    [in, string] WCHAR* FtDfsName,
    [in] DWORD ApiFlags,
    [in, out, unique] DFSM_ROOT_LIST** ppRootList
);

```

**ServerName:** The pointer to a null-terminated Unicode string. This is the host name DFS root target to be removed.

**DcName:** The pointer to a null-terminated Unicode string. For a domainv1-based DFS namespace, this string contains the host name of the DC to be used by the DFS root targets being removed for getting or updating DFS metadata for the DFS namespace. This parameter MAY be a NULL pointer; otherwise, it MUST be the PDC for the domain of the DFS namespace.

**RootShare:** The pointer to a null-terminated Unicode DFS root target share name string. The share is not removed automatically when the method is successful; it MUST be removed explicitly as needed.

**FtDfsName:** The pointer to a null-terminated Unicode string that contains the DFS namespace in which the operation is to be performed. It MAY be different from the *RootShare*.

**ApiFlags:** The only supported bit in the *ApiFlags* parameter is DFS\_FORCE\_REMOVE.

Value	Meaning
DFS_FORCE_REMOVE 0x80000000	Removes the named DFS root target from the namespace's directory service metadata only.

All other bits are reserved and MUST NOT be used. If reserved bits are specified, the server SHOULD [fail](#) the call.

**ppRootList:** On success, returns a list of DFS root targets in the domain-based DFS namespace which the client will be responsible for notifying about the change in the DFS namespace. See section [3.2.4.3.2](#). The list MAY be empty if the server has performed the notification. [fail](#)

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000002 ERROR_FILE_NOT_FOUND	The specified DFS root target was not found as a target of the specified DFS namespace.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000057 ERROR_INVALID_PARAMETER	An incorrect parameter was specified.

Return value/code	Description
0x00000490 ERROR_NOT_FOUND	The specified DFS rootnamespace does not exist.

The server MUST verify the existence of the DFS namespace that the *FtDfsName* parameter specifies. If that existence check fails, the server MUST return ERROR\_NOT\_FOUND.

The server MUST verify the existence of the DFS root target of the DFS namespace that the *ServerName* and *RootShare* parameters specify. If that existence check fails, the server MUST return ERROR\_FILE\_NOT\_FOUND.

The server MUST support deleting a DFS namespace without first requiring removal of all the DFS links in it.

If the *DcName* parameter is not NULL, then it MUST be the PDC for the domain of the DFS namespace.

The server MAY support DFS\_FORCE\_REMOVE on member servers. <115> If it is not supported and DFS\_FORCE\_REMOVE is specified, the server MUST return a failure.

If DFS\_FORCE\_REMOVE is not specified, the server MUST verify it is the host specified by the *ServerName* and *RootShare* parameters. If it is not, the server MUST return ERROR\_NOT\_FOUND.

If DFS\_FORCE\_REMOVE is not specified, the server SHOULD <116> also remove any local information related to hosting the removed root target. If DFS\_FORCE\_REMOVE is specified, the server MUST NOT do so.

The effect of DFS\_FORCE\_REMOVE is to clean up after the named root target has become nonfunctional and is unable to remove itself from the namespace.

The server MUST remove the root target of the domain-based DFS namespace specified by the *ServerName* and *RootShare* parameters by updating the **remoteServerName** attribute of the namespace's object (as specified in section 2.3.3) in the root target. If the last DFS root target is being removed, then the server SHOULD NOT remove the object of the namespace; the client invoking the method MUST do this. <117>

The server SHOULD remove any intermediate directories and reparse points that were part of the namespace.

The server MUST update the following fields in the domainv1-based DFS metadata.

Operation	DFS metadata changes required
Remove a namespace.	Removes the object of DFS namespace.
Remove a root target.	Updates the <b>TargetCount</b> in the existing <a href="#">DFSTargetListBLOB</a> , removes the <a href="#">TargetEntryBLOB</a> , updates the <a href="#">DFSTargetListBLOBSize</a> , updates the <a href="#">BLOBDataSize</a> of the <a href="#">DFSNamespaceRootBLOB</a> , and removes the root target from the <b>remoteServerName</b> attribute in the object.

The server MUST synchronously update the DFS metadata of the namespace.

If DFS root scalability mode is not enabled, then the server MUST do one of the following:

- Notify other DFS root targets of the change in DFS metadata by asynchronously issuing a [NetrDfsSetInfo \(Opnum 3\)](#) method with the *Level* parameter 101 and with the **State** field of [DFS\\_INFO\\_101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE. The returned *ppRootList* parameter MUST be empty.
- Perform no notification of the other root targets, returning a list of DFS root targets to the client in the *ppRootList* parameter.

### 3.1.4.3.3 NetrDfsFlushFtTable (Opnum 18)

For information about this method, see [3.3.4.3.2](#).

### 3.1.4.4 Stand-Alone Namespace Methods

#### 3.1.4.4.1 NetrDfsAddStdRoot (Opnum 12)

The **NetrDfsAddStdRoot (Opnum 12)** method creates a new stand-alone DFS namespace. [<118>](#) [<119>](#)

The **NetrDfsAddStdRoot** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsAddStdRoot(
    [in, string] WCHAR* ServerName,
    [in, string] WCHAR* RootShare,
    [in, string] WCHAR* Comment,
    [in] DWORD ApiFlags
);
```

**ServerName:** The pointer to a null-terminated Unicode string. This is the host name of the new DFS root target.

**RootShare:** The pointer to a null-terminated Unicode string. This is the new DFS root target share name as well as the DFS namespace name. The share MUST already exist.

**Comment:** The pointer to a null-terminated Unicode string that contains a comment associated with the DFS namespace. Used for informational purposes, this string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality. This parameter MAY be a NULL pointer.

**ApiFlags:** This parameter is reserved for future use and is ignored by the server.

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000050 ERROR_FILE_EXISTS	The DFS namespace that the <i>ServerName</i> and <i>RootShare</i> parameters specify already exists. <a href="#">&lt;120&gt;</a>

Return value/code	Description
0x000000B7 ERROR_ALREADY_EXISTS	The DFS namespace that the <i>ServerName</i> and <i>RootShare</i> parameters specify already exists.<121>
0x00000906 NERR_NetNameNotFound	The share that the <i>RootShare</i> parameter specifies does not already exist.

On receiving this method, the server MUST do the following:

- If there is any entry in the **NamespaceList** with the **NamespaceName** matching *RootShare*, then the RPC method MUST fail with either ERROR\_FILE\_EXISTS (0x00000050) or ERROR\_ALREADY\_EXISTS (0x000000B7).
- If the share that the *RootShare* parameter specifies does not already exist, the RPC method MUST fail with NERR\_NetNameNotFound (0x00000906).
- Create the **Namespace** object, and insert it into the **NamespaceList**. The **Namespace** object MUST be initialized as follows.
  - **Namespace.NamespaceName** is set to *RootShare*.
  - **Namespace.NamespaceType** is set to stand-alone.
  - **Namespace.GenerationGUID** is set with a GUID.
  - Create a **NamespaceElement** object and insert it into **Namespace.NamespaceElementsList**.
  - **NamespaceElementsList.NamespaceElement** is initialized as follows.
    - **NamespaceElement.Properties** is set to 0.
    - **NamespaceElement.State** is set to DFS\_VOLUME\_STATE\_OK.
    - **NamespaceElement.Comment** is set to **Comment**.
    - **NamespaceElement.ReferralTTL** is set to 300 seconds.
    - **NamespaceElement.SecurityDescriptor** is set to none.
    - Create a **Target** object, insert it into **NamespaceElement.TargetsList** and update **TargetsList.TargetCount** to 1.
    - **TargetsList.Target** object is initialized as follows.
      - **Target.PriorityRank** is set to 0.
      - **Target.PriorityClass** is set to DfsSiteCostNormalPriorityClass.
      - **Target.State** is set to DFS\_STORAGE\_STATE\_ONLINE.
      - **Target.ServerName** is set to *ServerName*.
      - **Target.ShareName** is set to *RootShare*.
- The server MUST synchronously insert the **Namespace** object into the local information store.

### 3.1.4.4.2 NetrDfsRemoveStdRoot (Opnum 13)

The **NetrDfsRemoveStdRoot (Opnum 13)** method deletes the specified stand-alone DFS namespace. [<122>](#) The DFS namespace can be removed without first removing all of the links in it.

The **NetrDfsRemoveStdRoot** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsRemoveStdRoot(  
    [in, string] WCHAR* ServerName,  
    [in, string] WCHAR* RootShare,  
    [in] DWORD ApiFlags  
);
```

**ServerName:** The pointer to a null-terminated Unicode string. This is the host name of the DFS root target to be removed.

**RootShare:** The pointer to a null-terminated Unicode DFS root target share name string. This is also the DFS namespace name. The share is not removed automatically when the method is successful; it **MUST** be removed explicitly, as needed.

**ApiFlags:** This parameter is reserved for future use and is ignored by the server.

**Return Values:** The method **MUST** return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x00000490 ERROR_NOT_FOUND	The DFS namespace that the <i>ServerName</i> and <i>RootShare</i> parameters specify does not already exist.

The server **MUST** support the removal of a DFS namespace without requiring that all of the DFS links be removed first.

On receiving this method, the server **MUST** do the following:

- If there is no entry in the **NamespaceList** with the **NamespaceName** matching *RootShare*, then the RPC method **MUST** fail with ERROR\_NOT\_FOUND (0x00000490).
- Remove the **Namespace** object corresponding to the *RootShare* from the **NamespaceList**.
- Remove the **Namespace** object from the local information store.

The server **SHOULD** remove any intermediate directories and reparse points that were part of the namespace.

### 3.1.4.4.3 NetrDfsAddStdRootForced (Opnum 15)

The **NetrDfsAddStdRootForced (Opnum 15)** method creates a new stand-alone DFS namespace without checking for the availability and accessibility of the specified share. [<123>](#)[<124>](#)[<125>](#)

The **NetrDfsAddStdRootForced** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsAddStdRootForced(  
    [in, string] WCHAR* ServerName,  
    [in, string] WCHAR* RootShare,  
    [in, string] WCHAR* Comment,  
    [in, string] WCHAR* Share  
);
```

**ServerName:** The pointer to a null-terminated Unicode string. This is the host name of the new DFS root target.

**RootShare:** The pointer to a null-terminated Unicode DFS root target share name string. This is also the DFS namespace name. This method does not create the share; it MUST be created separately.

**Comment:** The pointer to a null-terminated Unicode string that contains a comment associated with the DFS namespace. Used for informational purposes, this string has no protocol-specified restrictions on length or content. The comment is meant for human consumption and does not affect server functionality. This parameter MAY be a NULL pointer.

**Share:** The pointer to a null-terminated Unicode string that contains the local file system path corresponding to the share on the server receiving the RPC method, in the following form:

<X>:\<path>

where <X> is a drive letter (a single character from A to Z) and <path> is a file system path whose leaf component is a directory.

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.
0x000000B7 ERROR_ALREADY_EXISTS	The DFS namespace that the <i>ServerName</i> and <i>RootShare</i> parameters specify already exists.

The support for this method is optional. If supported, then the server MUST support the ability to create a DFS namespace even when the share that the *RootShare* parameter specifies is not available or accessible.

On receiving this method, the server MUST do the following.

- If there is any entry in the **NamespaceList** with the **NamespaceName** matching *RootShare*, then the RPC method MUST fail with ERROR\_ALREADY\_EXISTS (0x000000B7).

- Create and initialize the **Namespace** object, as specified in section [3.1.4.4.1](#), and insert it into the **NamespaceList**.
- The server MUST synchronously insert the **Namespace** object into the local information store.

### 3.1.4.5 Domain-Based Namespace Methods

#### 3.1.4.5.1 NetrDfsGetDcAddress (Opnum 16)

The **NetrDfsGetDcAddress (Opnum 16)** method returns the DC host name that is used by the DFS server to which the RPC method is issued. [<126>](#) The client MUST use this DC to create a domain-based DFS namespace, add a root target to a domain-based DFS namespace, remove a root target from a domain-based DFS namespace, or remove a domain-based DFS namespace.

The **NetrDfsGetDcAddress** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsGetDcAddress (
    [in, string] WCHAR* ServerName,
    [in, out, string] WCHAR** DcName,
    [in, out] BOOLEAN* IsRoot,
    [in, out] unsigned long* Timeout
);
```

**ServerName:** A pointer to a null-terminated Unicode string. This is the host name of the server to which the RPC method is issued. [<127>](#)

**DcName:** A null-terminated Unicode string that contains the DC host name when the **NetrDfsGetDcAddress** method is successful. [<128>](#)

**IsRoot:** A pointer to a Boolean value, set to TRUE on return if the server hosts any DFS root target, and FALSE otherwise. [<129>](#)

**Timeout:** A pointer to an unsigned 32-bit integer value indicating the count of seconds for which the server will use the DC that is returned to access DFS metadata. [<130>](#)

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [\[MS-ERREF\]](#) section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.

A server MAY [<131>](#) implement this method if it supports domain-based DFS namespaces.

In the *DcName* parameter, the server SHOULD return the host name of the DC it is using to access DFS metadata for any domain-based DFS namespace that the server is hosting. If the server is not currently using a DC, it MUST determine a DC and return its name.

The server SHOULD also return a time-out value, in seconds, that is equal to the length of time that the server will be using the DC in the *Timeout* parameter, assuming that another RPC method does not change it.

The server uses the *IsRoot* parameter to specify whether it supports the ability to host more than one DFS namespace, and to indicate whether it is currently hosting a DFS namespace. If the server supports the ability to host more than one DFS namespace, it MUST return a value of FALSE in the *IsRoot* parameter, regardless of whether it is actually hosting a DFS namespace. If the server does not support the ability to host more than one DFS namespace, and if it currently hosts a DFS namespace, it SHOULD return a value of TRUE in the *IsRoot* parameter; otherwise, it SHOULD return FALSE.

### 3.1.4.5.2 NetrDfsSetDcAddress (Opnum 17)

The **NetrDfsSetDcAddress (Opnum 17)** method instructs the server receiving the RPC method to use the specified DC for DFS metadata accesses for domain-based DFS namespaces. <132>

The **NetrDfsSetDcAddress** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsSetDcAddress (
    [in, string] WCHAR* ServerName,
    [in, string] WCHAR* DcName,
    [in] DWORD Timeout,
    [in] DWORD Flags
);
```

**ServerName:** The pointer to a null-terminated Unicode string. This is the host name of the server to which the RPC method is issued.

**DcName:** The pointer to a null-terminated Unicode DC host name string.

**Timeout:** The time period, in seconds, that the server uses the specified DC when storing and retrieving domain-based DFS metadata. This is valid only when the NET\_DFS\_SETDC\_TIMEOUT bit of the *Flags* parameter is set.

**Flags:** The bit field specifying additional operations to perform. Possible values are as follows.

Value	Meaning
NET_DFS_SETDC_FLAGS 0x00000000	Indicates that no additional operation is requested.
NET_DFS_SETDC_TIMEOUT 0x00000001	Sets the time-out value based on the <i>Timeout</i> parameter.
NET_DFS_SETDC_INIT_PKT 0x00000002	Instructs the called server to reload its DFS metadata from the specified DC.

All other bits are reserved and MUST NOT be used. If reserved bits are specified, the server MAY fail the call with an implementation-defined failure value. <133>

**Return Values:** The method MUST return 0 on success and a nonzero error code on failure. The method can return any specific error code value, as specified in [MS-ERREF] section 2.2. The most common error codes are listed in the following table.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.

Return value/code	Description
0x00000005 ERROR_ACCESS_DENIED	Permission to perform the operation was denied.

Servers MAY choose not to implement this method or implement it as a method with no effect that returns ERROR\_SUCCESS.<134>

Otherwise, the server MUST update the DC it uses for accessing DFS metadata for the domain-based DFS namespace it is hosting with the specified DC. If no time-out is specified in the *Timeout* parameter (NET\_DFS\_SETDC\_TIMEOUT is not set in the *Flags* parameter), the server MUST use its default time-out. The DC the server should use at the end of this time-out is implementation-defined.

When NET\_DFS\_SETDC\_INIT\_PKT is set in the *Flags* parameter, the server SHOULD initiate a background synchronization of the domain-based DFS namespace it is hosting with either the DC specified by this method or the default DC the server is using. This MUST be treated as functionally equivalent to receiving a [NetrDfsSetInfo \(Opnum 3\)](#) method with the *Level* parameter value 101 and the *State* field of [DFS\\_INFO 101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE.<135>

### 3.1.5 Timer Events

No protocol timer events are required on the client beyond the timers required in the underlying **RPC transport**.

### 3.1.6 Other Local Events

No additional local events are used on the client beyond the events maintained in the underlying RPC transport.

## 3.2 Client Details

### 3.2.1 Abstract Data Model

None.

### 3.2.2 Timers

No protocol timers are required beyond those used internally by the RPC method to implement resiliency to network outages, as specified in [\[MS-RPCE\]](#).

### 3.2.3 Initialization

The client creates an RPC binding handle to the server RPC method **endpoint** when an RPC method is called. For more information on binding handles, see [\[C706\]](#). The client MAY create a separate binding handle for each method invocation, or it MAY reuse a binding handle for multiple invocations. The client MUST create an authenticated RPC binding handle.<136>

### 3.2.4 Message Processing Events and Sequencing Rules

The client MUST pass any error received from the invocation of an RPC method to the application that issued the RPC call.

On successful completion of methods returning lists of servers to notify ([NetrDfsAdd2](#), [NetrDfsRemove2](#), and [NetrDfsSetInfo2](#)), the application SHOULD notify the servers that the namespace metadata has been updated. This is done by issuing the [NetrDfsSetDcAddress](#) method to each server, specifying NET\_DFS\_SETDC\_INITPKT on the *Flags* parameter.

As specified in section [3.1.4.5.2](#) and its references, issuing the **NetrDfsSetDcAddress** method will cause the targeted server to update the cached copy of the metadata it may hold. If this notification is not delivered, the specified servers could be unaware of the namespace metadata update for an indeterminate period of time. Such a failure to deliver the notification is normal, however, and may be due to client or application failure (for example a crash or a power or network outage).

The server recovers from notification failure because of the updating requirement in section [3.1.4](#). The updating requirement states the preconditions that a server MUST satisfy before processing an RPC method.

### 3.2.4.1 Basic Methods

#### 3.2.4.1.1 NetrDfsAdd (Opnum 1)

If a NetrDfsAdd call to the DFS root target fails with ERROR\_NOT\_SUPPORTED (0x00000032), an application may use this as an indication to issue the [NetrDfsAdd2](#) method instead. [<137>](#)

#### 3.2.4.1.2 NetrDfsRemove (Opnum 2)

If a NetrDfsRemove call fails with ERROR\_NOT\_SUPPORTED (0x00000032), an application may use this as an indication to issue the [NetrDfsRemove2](#) method. [<138>](#)

#### 3.2.4.1.3 NetrDfsSetInfo (Opnum 3)

If a NetrDfsSetInfo call fails with ERROR\_NOT\_SUPPORTED (0x00000032), an application may use this as an indication to issue the [NetrDfsSetInfo2](#) method instead. [<139>](#)

#### 3.2.4.1.4 NetrDfsEnum (Opnum 5) and NetrDfsEnumEx (Opnum 21)

An application may use either the NetrDfsEnum or the NetrDfsEnumEx method to enumerate roots and links. The application may use the value that [NetrDfsManagerGetVersion](#) returns, to determine the enumeration method to use. [<140>](#)[<141>](#)

Due to the possibility of concurrent updates to the DFS namespace, an application SHOULD NOT assume completeness or uniqueness of the results returned when resuming an enumeration (for more information on NetrDfsEnum, see section [3.1.4.1.7](#)). [<142>](#)

### 3.2.4.2 Extended Methods

#### 3.2.4.2.1 NetrDfsAdd2 (Opnum 19)

An application MUST determine the PDC of a DFS root target server of the DFS namespace specified by the *DfsEntryPath* parameter and invoke the [NetrDfsAdd2](#) method specifying the PDC.

If successful, the application SHOULD issue notifications to each server returned in the *ppRootList* parameter, as specified in section [3.2.4](#).

### 3.2.4.2.2 NetrDfsRemove2 (Opnum 20)

An application MUST determine the PDC of a DFS root target server of the DFS namespace specified by the *DfsEntryPath* parameter and invoke the NetrDfsRemove2 method specifying the PDC.

If successful, the application SHOULD issue notifications to each server returned in the *ppRootList* parameter, as specified in section [3.2.4](#).

### 3.2.4.2.3 NetrDfsSetInfo2 (Opnum 22)

An application MUST determine the PDC of a DFS root target server of the DFS namespace specified by the *DfsEntryPath* parameter and invoke the NetrDfsSetInfo2 method specifying the PDC.

If successful, the application SHOULD issue notifications to each server returned in the *ppRootList* parameter, as specified in section [3.2.4](#).

## 3.2.4.3 Root Target Methods

### 3.2.4.3.1 NetrDfsAddFtRoot (Opnum 10)

The NetrDfsAddFtRoot method is supported only for a domainv1-based DFS namespace scenario.

An application MUST perform the following steps before invoking the NetrDfsAddFtRoot method:

1. Determine the PDC of the domain of the DFS root target server that the *ServerName* parameter specifies.
2. If an object of type *FTDfs* with the name of the domain-based DFS namespace does not already exist in the **DFS Configuration Container**, create a new object for the domain-based DFS namespace, as specified in section [2.3.3](#).
3. Update the ACL on the object of the DFS namespace to permit read/write access by the DFS root target server.
4. Call the [NetrDfsFlushFtTable](#) method on the PDC, specifying the DFS namespace name.
5. If all prior steps succeeded without error, then the client MUST issue the [NetrDfsSetDcAddress \(Opnum 17\)](#) method to each server that the *ppRootList* parameter returns. [<143><144>](#)

### 3.2.4.3.2 NetrDfsRemoveFtRoot (Opnum 11)

An application MUST determine the PDC of the domain of the DFS root target server that the *ServerName* parameter specifies. [<145>](#) If the *ApiFlags* parameter is not DFS\_FORCE\_REMOVE, the application MUST issue the RPC method to the DFS root target server that the *ServerName* parameter specifies; otherwise, the application MUST issue the RPC method to the PDC.

This method is supported only for a domainv1-based DFS namespace scenario. If a client application attempts to use it on a domainv2-based DFS namespace or target, the server MUST fail with a return value of ERROR\_NOT\_SUPPORTED.

If all prior steps succeeded without error, then the application MUST perform the following steps:

1. Invoke the [NetrDfsSetDcAddress](#) method to each server returned in the *ppRootList* parameter. [<146>](#)

2. Update the ACL on the object (as specified in section [2.3.3](#)) of the DFS namespace to remove read/write access by the DFS root target server.
3. Remove the object itself if the **remoteServerName** attribute of the DFS namespace object (as specified in section [2.3.3](#)) has exactly one value in it.
4. Call the [NetrDfsFlushFtTable](#) method on the PDC, specifying the DFS namespace name.

### 3.2.5 Timer Events

No protocol timer events are required on the client beyond those required in the underlying RPC call transport.

### 3.2.6 Other Local Events

No additional local events are used on the client beyond those maintained in the underlying RPC transport.

## 3.3 Domain Controller Details

A DC hosting a DFS root target MUST conform to the specification in section [3.1](#).

In addition, the DFS server on a DC MUST do the following:

- Receive and respond to DFS root and DFS link referral requests for any domain-based DFS namespace in the domain. The DC need not be a DFS root target for the domain-based DFS namespace identified in the referral request.
- Receive and respond to the RPC methods, as specified in section [3.3.4](#).

### 3.3.1 Abstract Data Model

A DFS server on a DC MAY maintain the following data item:

- **ReferralCache:** A referral cache that is used when distributing referrals for domain-based DFS namespaces. This is for use by the DFS Referral Protocol, as specified in [\[MS-DFSC\]](#).

### 3.3.2 Timers

No protocol timers are required beyond those used internally by RPC to implement resiliency to network outages, as specified in [\[MS-RPCE\]](#).

### 3.3.3 Initialization

No initialization is required beyond that used internally by RPC, as specified in [\[MS-RPCE\]](#).

### 3.3.4 Message Processing Events and Sequencing Rules

A DC MAY [<147>](#) itself be a DFS root target. In such cases, it MUST process RPC methods, as specified in section [3.1](#). In addition, some methods SHOULD be specially supported, as specified in the following topics.

### 3.3.4.1 Basic Methods

#### 3.3.4.1.1 NetrDfsRemoveRootTarget (Opnum 24)

A DFS server on a DC MUST support the DFS\_FORCE\_REMOVE value (0x80000000) for the *ApiFlags* parameter. DFS\_FORCE\_REMOVE value is used to delete a domain-based DFS namespace when the root target servers of the namespace are no longer available (for example, they have been decommissioned).

### 3.3.4.2 Extended Methods

#### 3.3.4.2.1 NetrDfsEnumEx (Opnum 21)

A DFS server on a DC SHOULD support the *Level* parameter 200. The DFS server MUST validate the *DfsEntryPath* parameter against the name of the domain to which the DC is joined, and fail with ERROR\_INVALID\_NAME (0x0000007B) if it does not match. The DFS server then returns the list of domain-based DFS namespaces in the domain. This MUST be returned by performing an LDAP search for objects on the domain controller under the container. The container has the following DN:

```
CN=Dfs-Configuration,CN=System,<domain>
```

where *<domain>* is the DN of the domain. For details and more information, see section [2.3.1.<148>](#)

### 3.3.4.3 Root Target Methods

#### 3.3.4.3.1 NetrDfsRemoveFtRoot (Opnum 11)

A DFS server on a DC MUST support the DFS\_FORCE\_REMOVE value (0x80000000) for the *ApiFlags* parameter. The DFS\_FORCE\_REMOVE value is used to delete a domain-based DFS namespace when the root target servers of the namespace are no longer available (for example, decommissioned).

#### 3.3.4.3.2 NetrDfsFlushFtTable (Opnum 18)

The **NetrDfsFlushFtTable** method instructs the DFS server on a DC to purge the specified domainv1-based DFS entry from any DFS root referral cache it may have.

**Note** This method MUST fail on non-DC servers, as specified in this section.

The **NetrDfsFlushFtTable** method uses the following MIDL syntax.

```
NET_API_STATUS NetrDfsFlushFtTable(  
    [in, string] WCHAR* DcName,  
    [in, string] WCHAR* wszFtDfsName  
);
```

**DcName:** The pointer to a null-terminated Unicode string that contains the host name of the DC to which the RPC method is issued.

**wszFtDfsName:** The pointer to a null-terminated Unicode string that contains the name of the domain-based DFS namespace.

**Return Values:** This method MUST return 0 on success and a nonzero error code on failure. The values transmitted in this field are implementation-specific. For protocol purposes, all nonzero values MUST be treated as equivalent failures.

**Note** This method MUST return ERROR\_NOT\_SUPPORTED on non-DC servers.

Return value/code	Description
0x00000000 ERROR_SUCCESS	Successful completion.
0x00000032 ERROR_NOT_SUPPORTED	Operation not supported. This MUST be returned if the server does not implement the method.

The server MAY choose not to implement this method. [<149>](#) If it does, ERROR\_NOT\_SUPPORTED MUST be returned.

### 3.3.5 Timer Events

No protocol timer events are required on the client beyond the timers required in the underlying RPC transport.

### 3.3.6 Other Local Events

No additional local events are used on the client beyond the events maintained in the underlying RPC transport.

## 4 Protocol Examples

The following examples for domainv1 are in a Windows Server 2003 operating system domain; the client used is Windows XP operating system Service Pack 2 (SP2). The member servers and domain controllers used in the example are all Windows Server 2003 operating system with Service Pack 1 (SP1).

For domainv2, the client is Windows Vista operating system. The member servers and domain controllers in this scenario are all Windows Server 2008 operating system.

### 4.1 Creating a New Domainv1-Based DFS Namespace

The following example describes the steps used to create a new domainv1-based DFS namespace. The namespace name is testroot1, to be created on a server named CFS-41X-2C02 within the dfsn-dev.microsoft.com domain.

1. A client determines whether a new domainv1-based DFS namespace is being created, or a new DFS root target is being added to an existing domain-based DFS namespace, by issuing an LDAP search for the object corresponding to the domainv1-based DFS namespace. The following illustration shows the LDAP search parameters that do this.
2. Because the domainv1-based DFS namespace does not already exist, the DC fails the LDAP search with LDAP\_NO\_SUCH\_OBJECT.
3. The client creates an object for the new domainv1-based DFS namespace.
4. Object creation is successful.
5. The client updates the ACL on the object to permit the new DFS root target to update the object.
6. The ACL change on the object is successful.
7. The client issues a [NetrDfsAddFtRoot](#) method to the DFS root target server.
8. The DFS root target creates the DFS metadata required for the new domainv1-based DFS namespace and updates the DFS metadata in the object corresponding to the DFS namespace. This is shown as an LDAP modify operation to the PDC for the domain. The following illustration shows the LDAP modify parameters that do this.
9. The DFS metadata write is successful.
10. The DFS root target completes the [NetrDfsAddFtRoot](#) method to the client.

The following illustration shows the sequence of events.

**Figure 2: Creating a new domainv1-based DFS namespace**

## 4.2 Adding a Root Target to an Existing Domainv1-Based DFS Namespace

The following example describes the steps used to create a new root target in an existing domainv1-based DFS namespace.

1. The client determines whether a new domainv1-based DFS namespace is being created or a new DFS root target is being added to an existing domainv1-based DFS namespace, by issuing an LDAP search for the object corresponding to the domainv1-based DFS namespace to the PDC.

2. Because the domainv1-based DFS namespace already exists, the LDAP search is successful.
3. The client updates the ACL on the object to permit the new DFS root target CFS-41X-2C03 to update the object.
4. The ACL change on the object is successful.
5. The client issues a [NetrDfsAddFtRoot](#) method to the new DFS root target server CFS-41X-2C03.
6. The DFS root target server CFS-41X-2C03 creates the DFS metadata required for the new domainv1-based DFS namespace and writes it to the PDC for the domain. The following illustration shows the LDAP modify parameters that do this.
7. The DFS metadata write is successful.
8. The DFS root target CFS-41X-2C03 completes the [NetrDfsAddFtRoot](#) method to the client.

The following illustration shows the sequence of events.

**Figure 3: Adding a root target to an existing domainv1-based DFS namespace**

### 4.3 Adding a New Link to a Domain-Based DFS Namespace

The following example describes the steps for adding a new DFS link to an existing domainv1-based DFS namespace that has two root targets. The illustration in this example also shows how the DFS root target uses [NetrDfsSetInfo](#), *Level* parameter 101, and `DFS_VOLUME_STATE_RESYNCHRONIZE` to update the DFS metadata of the domain-based DFS namespace with the new DFS link information, and then notifies the other root targets.

1. A client issues a [NetrDfsAdd](#) RPC method to the DFS root target CFS-41X-2C02 for the domainv1-based DFS namespace.

2. The DFS root target CFS-41X-2C02 issues an LDAP search operation to retrieve the **pKTGuid** attribute in the object for the domainv1-based DFS namespace to the PDC for the domain. The following illustration shows the DN of the object and the attribute searched.
3. The LDAP search is successful, and the value of the **PktGuid** attribute is returned.
4. The DFS root target CFS-41X-2C02 determines that the DFS metadata in its cache is up-to-date and determines whether the new link target is already in another DFS namespace. This is done by issuing the **NetrShareGetInfo** method, as specified in [\[MS-SRVS\]](#), specifying a *Level* parameter 1005 to the DFS link target CFS-44X-2B08 to check the link target share's properties. For more information on the **NetrShareGetInfo** method, see [\[MS-SRVS\]](#).
5. The **NetrShareGetInfo** RPC method returns an indication that the DFS link target share is not a DFS namespace. This information is used to determine the value of the `PKT_ENTRY_TYPE_OUTSIDE_MY_DOM` bit of the **Type** field of the [DFSRootOrLinkIDBLOB](#) (for more information, see section [2.3.3.1.1.2](#)) for the DFS link. For this example, the bit is set to 0.
6. DFS link target CFS-41X-2C02 issues an LDAP modify operation to the PDC with a new **pKTGuid** value and the updated DFS metadata containing the new DFS link information.
7. The LDAP modify operation is successful.
8. The [NetrDfsAdd](#) method invoked by the client completes successfully.
9. The DFS root target, which updated the DFS metadata, issues the **NetrDfsSetInfo** method with the *Level* parameter 101 and the **State** field of [DFS\\_INFO\\_101](#) set to `DFS_VOLUME_STATE_RESYNCHRONIZE` to all of the other root targets. CFS-41X-2C02, in this example, is notifying CFS-41X-2C03.
10. On receiving the **NetrDfsSetInfo** method, *Level* parameter 101, and `DFS_VOLUME_STATE_RESYNCHRONIZE`, CFS-41X-2C03 issues an LDAP search to the PDC to verify whether the DFS metadata in its cache is up-to-date.
11. The LDAP search operation is successful and contains the **pKTGuid** attribute's value.
12. CFS-41X-2C03 determines that the cached DFS metadata it has needs to be refreshed. It then issues an LDAP search operation to retrieve the value of the **pKT** attribute, which contains the actual DFS metadata.
13. The LDAP search is successful and contains the DFS metadata in the reply.
14. In this example, CFS-41X-2C03 performs the required changes to its local state by adding the new DFS link. The **NetrDfsSetInfo** method that CFS-41X-2C02 issued is then completed.

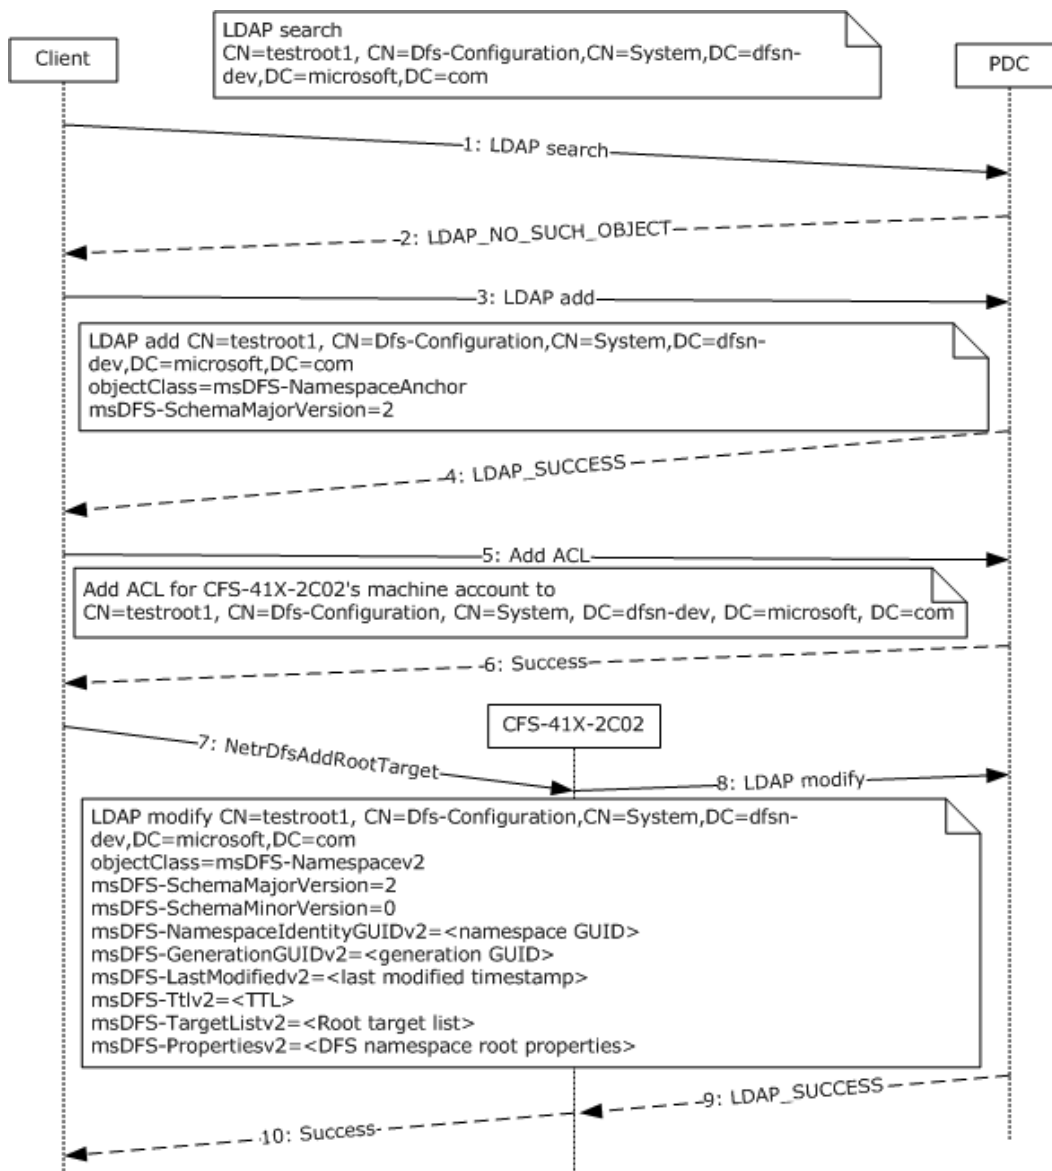

**Figure 4: Adding a new link to a domainv1-based DFS namespace**

#### 4.4 Creating a New Domainv2-Based DFS Namespace

The following example describes the steps used to create a new domainv2-based DFS namespace.

1. A client determines whether a new domainv2-based DFS namespace is being created or a new DFS root target is being added to an existing domainv2-based DFS namespace, by issuing an LDAP search for the object corresponding to the domainv2-based DFS namespace. The following illustration shows the LDAP search parameters that do this.
2. Because the domainv2-based DFS namespace does not already exist, the DC fails the LDAP search with LDAP\_NO\_SUCH\_OBJECT.
3. The client creates an object for the new domainv2-based DFS namespace.
4. Object creation is successful.
5. The client updates the ACL on the object to permit the new DFS root target CFS-41X-2C02 to update the object.
6. The ACL change on the object is successful.
7. The client issues a [NetrDfsAddRootTarget](#) method to the DFS root target server.
8. The DFS root target server creates a new DFS namespace LDAP entry with the DFS namespace anchor LDAP entry as its parent. The server also creates the DFS metadata required for the new domainv2-based DFS namespace and updates the DFS metadata in the object corresponding to the DFS namespace. This appears as an LDAP modify operation to the PDC for the domain. The following illustration shows the LDAP modify parameters that do this.
9. The DFS metadata write is successful.
10. The DFS root target completes the **NetrDfsAddRootTarget** method to the client.

The following illustration shows this sequence of events.

**Figure 5: Creating a new domainv2-based DFS namespace**

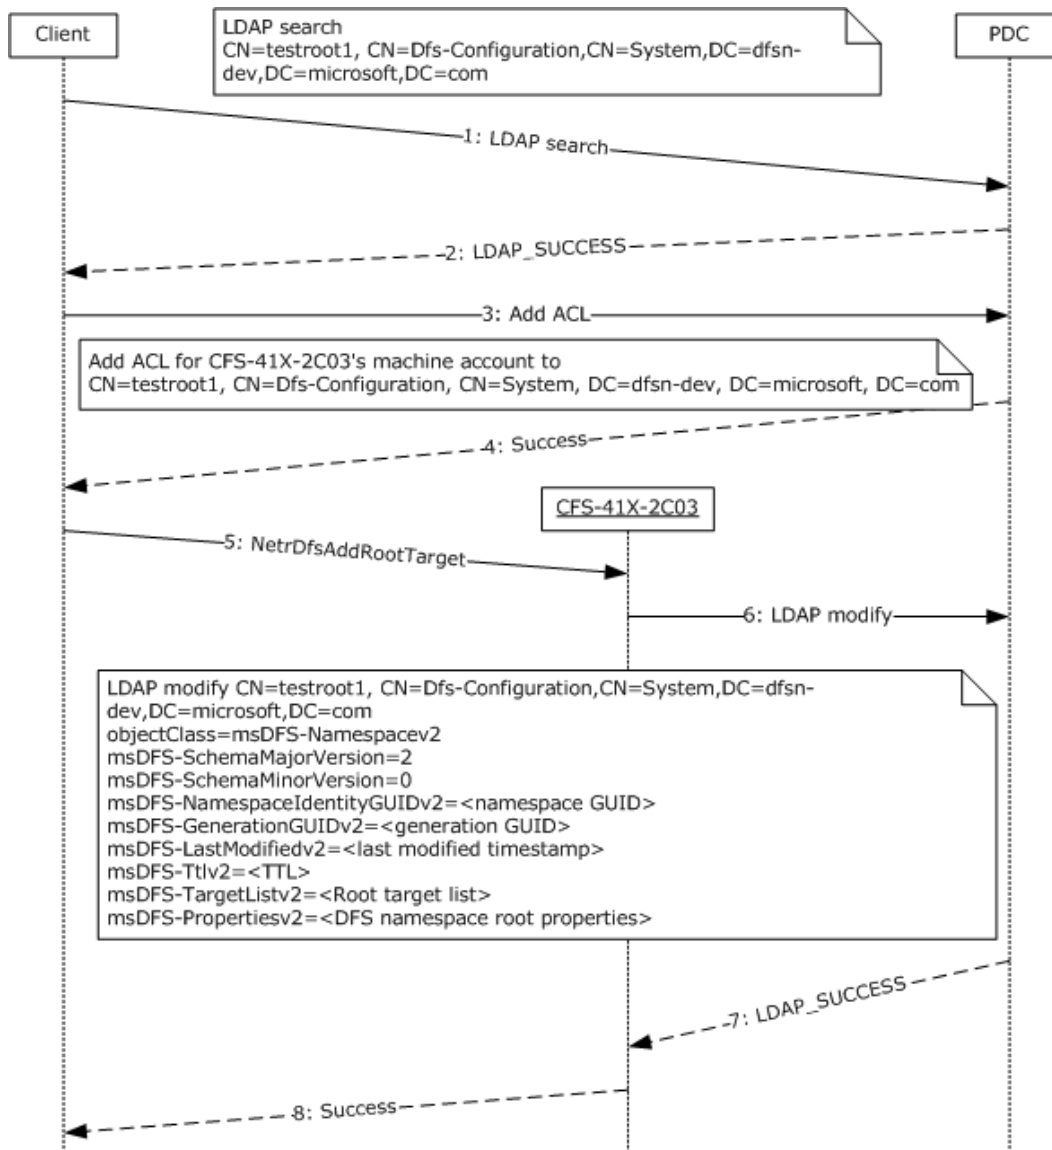

#### 4.5 Adding a Root Target to an Existing Domainv2-Based DFS Namespace

The following example describes the steps used to create a new root target in an existing domainv2-based DFS namespace.

1. The client determines whether a new domainv2-based DFS namespace is being created, or a new DFS root target is being added to an existing domainv2-based DFS namespace, by issuing an LDAP search for the object corresponding to the domainv2-based DFS namespace to the PDC.
2. Because the domainv2-based DFS namespace already exists, the LDAP search is successful.

3. The client updates the ACL on the object to permit the new DFS root target CFS-41X-2C03 to update the object.
4. The ACL change on the object is successful.
5. The client issues a [NetrDfsAddRootTarget](#) method to the new DFS root target server CFS-41X-2C03.
6. The DFS root target server CFS-41X-2C03 creates the DFS metadata required for the new domainv2-based DFS namespace and writes it to the PDC for the domain. The following illustration shows the LDAP modify parameters that do this.
7. The DFS metadata write is successful.
8. The DFS root target CFS-41X-2C03 completes the **NetrDfsAddRootTarget** method to the client.

The following illustration shows the sequence of events.

**Figure 6: Adding a root target to an existing domainv2-based DFS namespace**

#### 4.6 Adding a New Link to a Domainv2-Based DFS Namespace

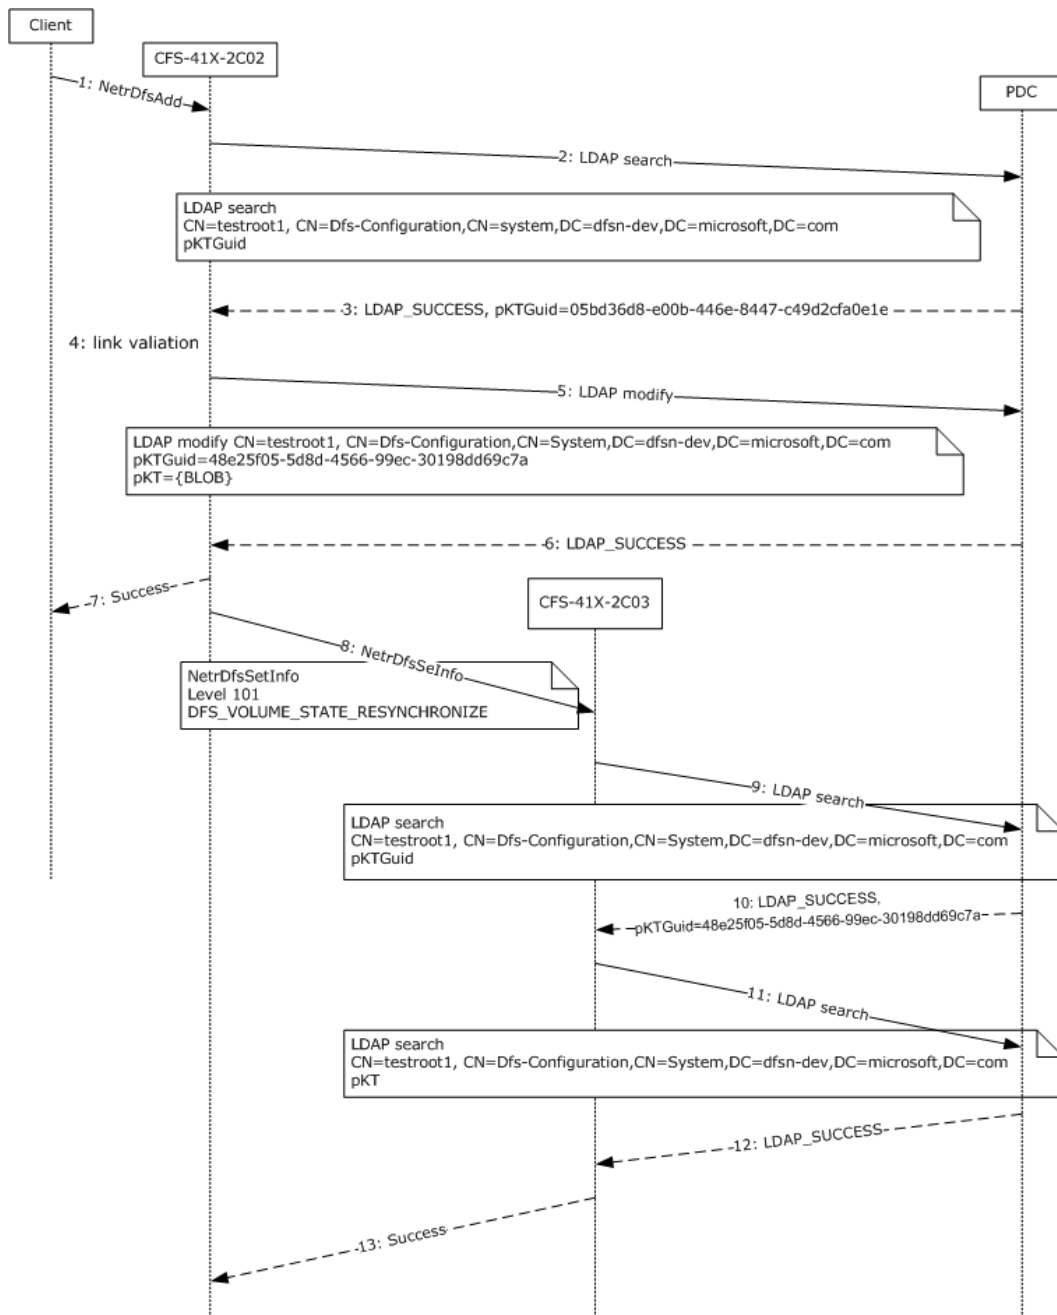

The following example describes the steps used to add a new DFS link to an existing domainv2-based DFS namespace with two root targets. The illustration in this example also shows how the DFS root target uses [NetrDfsSetInfo](#), `Level` parameter 101, and `DFS_VOLUME_STATE_RESYNCHRONIZE`, to update the DFS metadata of the domain-based DFS namespace with the new DFS link information, and then notifies the other root targets.

1. A client issues a [NetrDfsAdd](#) RPC method to the DFS root target CFS-41X-2C02 for the domainv2-based DFS namespace.
2. The DFS root target CFS-41X-2C02 performs either a full synchronization or an incremental synchronization. A full synchronization is performed if the DFS root target server is switching to a

new PDC or if the DC that the synchronization operation is currently using is different from that in the <uSNChanged, DC invocation ID> tuple that was saved at the start of a previous full synchronization for the DFS namespace. An incremental synchronization is performed if the DFS root target server is already syncing with the PDC.

3. An incremental synchronization is done by issuing an LDAP search operation for the DFS namespace LDAP entry subtree to determine whether in any of the object classes of msDFS-Namespave2, msDFS-Linkv2, or msDFS-DeletedLinkv2 the uSNChanged is greater than the saveduSNChanged value, where saveduSNChanged is the uSNChanged value from the tuple <uSNChanged, DC invocation ID> that was saved previously.
4. The DFS root target CFS-41X-2C02 determines that the DFS metadata in its cache is up-to-date and whether the new link points to another DFS namespace.
5. DFS link target CFS-41X-2C02 issues an LDAP modify operation to the PDC with a new identity GUID (msDFS-LinkIdentityGUID) value and the updated DFS metadata that contains the new DFS link information. The link identity GUID is set at DFS link creation time and does not change for the lifetime of the LDAP entry. It is used to locate the in-memory data structure that corresponds to the DFS link in the DFS metadata cache.
6. The LDAP modify operation is successful.
7. The **NetrDfsAdd** method invoked by the client completes successfully.
8. To perform a full synchronization to ensure that this is propagated to all other root targets, the DFS root target, which updated the DFS metadata, issues the **NetrDfsSetInfo** method, with the *Level* parameter 101 and the **State** field of [DFS\\_INFO\\_101](#) set to DFS\_VOLUME\_STATE\_RESYNCHRONIZE, to all of the other root targets. This is used to identify added or deleted DFS links. In this example, CFS-41X-2C02 is notifying CFS-41X-2C03.
9. On receiving the **NetrDfsSetInfo** method with *Level* parameter 101 and DFS\_VOLUME\_STATE\_RESYNCHRONIZE, CFS-41X-2C03 issues an LDAP search to the PDC to verify whether the DFS metadata in its cache is up-to-date. A different uSNChanged value from the <uSNChanged, DC invocation ID> tuple saved at the start of a previous full sync would indicate what has changed, and it would subsequently perform an incremental sync to propagate any DFS metadata change.
10. CFS-41X-2C03 determines that the cached DFS metadata it has needs to be refreshed. It then issues an LDAP search operation to retrieve the attributes associated with the msDFS-Linkv2 class, which contains the actual DFS metadata.
11. The LDAP search is successful and contains the DFS metadata in the reply.
12. In this example, CFS-41X-2C03 performs the required changes to its local state by adding the new DFS link. The **NetrDfsSetInfo** method that CFS-41X-2C02 issued is then completed.

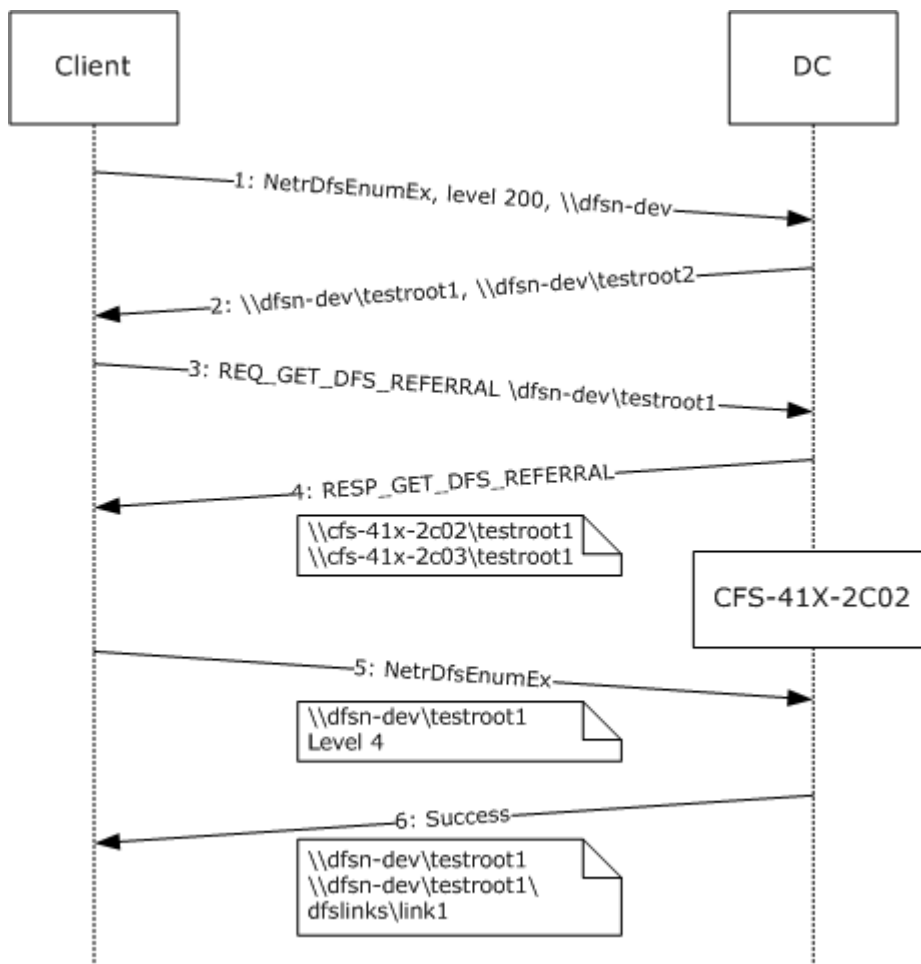

**Figure 7: Adding a new link to a domainv2-based DFS namespace**

#### 4.7 Enumerating DFS Links in a Domain-Based DFS Namespace

The following example describes the sequence of an interactive administration application that enumerates all domain-based DFS namespaces in a domain and all DFS links of a domain-based DFS namespace.

1. To enumerate all of the domain-based DFS namespaces in the dfsn-dev domain, the administration application issues the **NetrDfsEnumEx** RPC method with the *DfsEntryPath* parameter `\\dfs-dev` and *Level* parameter 200. This method is issued to the DC.
2. The DC returns two domain-based DFS namespaces in the domain: `\\dfs-dev\testroot1` and `\\dfs-dev\testroot2`.
3. The user decides to view information about the domain-based DFS namespace `\\dfs-dev\testroot1`. Before the administering application can issue the RPC method to obtain information about that DFS namespace, it must determine which DFS root target it will issue the RPC method to. This is done by issuing a DFS root referral request to the DC, as specified in [\[MSDFS\]](#).
4. The DC responds to the DFS root referral request with the two DFS root targets: `\\cfs-41x-2c02\testroot1` and `\\cfs-41x-2c03\testroot1`.
5. The **NetrDfsEnumEx** RPC method to obtain information about the DFS namespace `\\dfs-dev\testroot1` is then issued to the root target `cfs-41x-2c02`.
6. The root target returns the DFS root and one DFS link in the domain-based DFS namespace.

## Figure 8: Enumerating DFS links in a domainv1-based DFS namespace

### 4.8 DFS Metadata of a Domainv1-Based DFS Namespace

This example uses the following domainv1-based DFS namespaces:

- DFS root: `\\dfsn-dev\testroot1`
- DFS root targets: `\\cfs-41x-2c02\testroot1` and `\\cfs-41x-2c03\testroot1`
- DFS link: `\\dfsn-dev\testroot1\dfslinks\link1`
- DFS link target `\\cfs-44x-2b08\public`

The following illustration shows the hexadecimal dump of the DFS metadata for this domainv1-based DFS namespace. The offsets in the hexadecimal dump are used to explain the dump.

## 5 Security

### 5.1 Security Considerations for Implementers

The DFS: Namespace Management Protocol allows any user to establish a connection to the RPC server. The protocol uses the underlying RPC Protocol to retrieve the identity of the caller that made the method call, as specified in [\[MS-RPCE\]](#) section 3.3.3.4.3. Clients SHOULD create an authenticated RPC connection. Servers SHOULD use this identity to perform method-specific access checks. [<150>](#)

### 5.2 Index of Security Parameters

The only security parameter is Authentication Protocol, section [2.1](#).

## 6 Appendix A: Full IDL

The DFS: Namespace Management Protocol contains one interface, whose IDL definition is listed in this section.

```
import "ms-dtyp.idl";

/* ----- structures and methods described [MS-DFSNM], section 2 and 3 ----- */

[
    uuid(4fc742e0-4a10-11cf-8273-00aa004ae673),
    version(3.0),

    [in, unique, string]  NETDFS_SERVER_OR_DOMAIN_HANDLE pName,
    [out]                 PDFS_SUPPORTED_NAMESPACE_VERSION_INFO pVersionInfo);
}

```

## 7 Appendix B: Product Behavior

The information in this specification is applicable to the following Microsoft products or supplemental software. References to product versions include released service packs:

- Windows NT 4.0 operating system
- Windows NT Server 4.0 operating system
- Windows 2000 Server operating system
- Windows XP operating system
- Windows Server 2003 operating system
- Windows Server 2003 R2 operating system
- Windows Vista operating system
- Windows Server 2008 operating system
- Windows 7 operating system
- Windows Server 2008 R2 operating system
- Windows 8 operating system
- Windows Server 2012 operating system
- Windows 8.1 operating system
- Windows Server 2012 R2 operating system

Exceptions, if any, are noted below. If a service pack or Quick Fix Engineering (QFE) number appears with the product version, behavior changed in that service pack or QFE. The new behavior also applies to subsequent service packs of the product unless otherwise specified. If a product edition appears with the product version, behavior is different in that product edition.

Unless otherwise specified, any statement of optional behavior in this specification that is prescribed using the terms SHOULD or SHOULD NOT implies product behavior in accordance with the SHOULD or SHOULD NOT prescription. Unless otherwise specified, the term MAY implies that the product does not follow the prescription.

[<1> Section 1.3](#): Windows NT Server 4.0 supports only stand-alone DFS namespaces.

[<2> Section 1.5](#): Windows relies on manual coordination between human operators to ensure that only one DFS metadata modification is in progress at any time.

[<3> Section 1.7](#): The Windows RPC Protocol returns `RPC_S_PROCNUM_OUT_OF_RANGE` to notify the client that an RPC method is out of range, as specified in [\[MS-RPCE\]](#).

[<4> Section 2.2.2.12](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support ABDE mode.

[<5> Section 2.2.3.5](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support ABDE mode.

<6> [Section 2.2.3.7](#): Windows servers return a null GUID for stand-alone DFS namespaces.

<7> [Section 2.2.3.10](#): This level is supported only in Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

To identify the DFS metadata format in use, two mandatory attributes are defined in the schema to hold the major version (ldapDisplayName = msDFS-SchemaMajorVersion) and minor version (ldapDisplayName = msDFS-SchemaMinorVersion) numbers. The **rangeUpper** attribute in the attribute schema for these version number attributes determines the format of the DFS metadata supported in the forest. The value of these attributes determines the DFS metadata format in use for an existing DFS namespace. The implementation of a domainv2-based DFS namespace has rangeUpper=2, rangeLower=2 for the NamespaceMajorVersion; and rangeUpper=0, rangeLower=0 for the NamespaceMinorVersion.

A change to an existing, or the addition of a new, mandatory attribute increments the major version and sets the minor version to 0. A change to an existing, or the addition of a new, optional attribute increments the minor version without changing the major version.

The NamespaceMajorVersion and NamespaceMinorVersion determine the format of the DFS metadata supported in the forest. The following table applies only to Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

	NamespaceMajorVersion	NamespaceMinorVersion
Domainv1-based DFS	1	1
Domainv2-based DFS	2	0
Stand-alone DFS	1	2

<8> [Section 2.2.3.10](#): This level is supported only in Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

To identify the DFS metadata format in use, two mandatory attributes are defined in the schema to hold the major version (ldapDisplayName = msDFS-SchemaMajorVersion) and minor version (ldapDisplayName = msDFS-SchemaMinorVersion) numbers. The **rangeUpper** attribute in the attribute schema for these version number attributes determines the format of the DFS metadata supported in the **forest**. The value of these attributes determines the DFS metadata format in use for an existing DFS namespace. The implementation of a domainv2-based DFS namespace has rangeUpper=2, rangeLower=2 for the NamespaceMajorVersion and rangeUpper=0, rangeLower=0 for the NamespaceMinorVersion.

A change to an existing, or the addition of a new, mandatory attribute increments the major version and sets the minor version to 0. A change to an existing, or the addition of a new, optional attribute increments the minor version without changing the major version.

The NamespaceMajorVersion and NamespaceMinorVersion determine the format of the DFS metadata supported in the forest. The following table applies only to Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

	NamespaceMajorVersion	NamespaceMinorVersion
Domainv1-based DFS	1	1
Domainv2-based DFS	2	0

	<b>NamespaceMajorVersion</b>	<b>NamespaceMinorVersion</b>
Stand-alone DFS	1	2

<9> [Section 2.2.3.10](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support ABDE mode.

<10> [Section 2.2.4.3](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support ABDE mode.

<11> [Section 2.3.3.1.1](#): Windows 2000 Server performs a case-sensitive comparison of the name. Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 perform a case-insensitive comparison of the name.

<12> [Section 2.3.3.1.1.2](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 use the same name for the **ShortPrefix** field and the **Prefix** field. Windows 2000 Server stores an 8.3 name in the **ShortPrefix** field.

<13> [Section 2.3.3.1.1.2](#): Only Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support DFS referral site costing.

<14> [Section 2.3.3.1.1.2](#): Only Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support DFS root scalability mode.

<15> [Section 2.3.3.1.1.2](#): Only Windows Server 2003 with SP1, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support DFS client target fallback.

<16> [Section 2.3.3.1.1.3.1](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 always set this field to 0x00000002. Windows 2000 Server sets this field to 0x00000001 for DFS root targets and to 0x00000002 for DFS link targets.

<17> [Section 2.3.3.1.1.4](#): Only Windows 2000 Server uses the [SiteInformationBLOB](#). Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 preserve this BLOB if it already exists. When creating a new DFS namespace, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 create this BLOB with a **SiteEntryCount** of 0 and do not create any [SiteEntryBLOBs](#).

<18> [Section 2.3.3.1.1.4](#): Windows 2000 Server determines the site of a DFS root target or a DFS link target when it is added to a domain-based DFS namespace, and stores the target in this BLOB. The **NetDfsManagerReportSiteInfo** method, as specified in [\[MS-SRVS\]](#), is issued to the DFS root target server or the DFS link target server that were added to determine the site information.

<19> [Section 2.3.4.2](#): Windows does not preserve unrecognized values.

<20> [Section 2.3.4.2](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support Domainv2.

<21> [Section 2.3.4.2](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support Domainv2.

<22> [Section 2.3.4.2](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support Domainv2.

<23> [Section 2.3.4.3](#): Windows does not preserve unrecognized values.

<24> [Section 2.3.4.3](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support Domainv2.

<25> [Section 2.3.4.3](#): Only Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support Domainv2.

<26> [Section 3.1.1](#): Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 cache the DFS metadata as an optimization.

<27> [Section 3.1.3](#): Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 determine the PDC for the domain and initialize the PDCRoleHolder.

<28> [Section 3.1.3](#): Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 cache the DFS metadata as an optimization.

<29> [Section 3.1.4](#): Windows uses only the error code values, as specified in [\[MS-ERREF\]](#).

<30> [Section 3.1.4](#): This method is not supported in Windows NT Server 4.0 and Windows 2000 Server.

<31> [Section 3.1.4](#): This method is supported only in Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

<32> [Section 3.1.4](#): This method is supported only in Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

<33> [Section 3.1.4](#): This method is supported only in Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

<34> [Section 3.1.4](#): For historical reasons, Windows 2000 Server uses method opnums 7, 8, and 9 for local RPC calls to itself. These methods are never called over the network by Windows clients or servers (to another server).

Opnums reserved for local use apply to Windows as follows: opnums 7-9 are only used locally, never remotely, by Windows 2000 Server and not by any other Windows version.

<35> [Section 3.1.4.1.1](#): This method is not implemented in Windows NT Server 4.0.

<36> [Section 3.1.4.1.1](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 return ERROR\_NOT\_SUPPORTED (0x00000032).

<37> [Section 3.1.4.1.2](#): The following table gives the return value of [NetrDfsManagerGetVersion](#) for different versions of Windows.

Windows Version	Return Value
Windows NT Server 4.0	0x00000001

Windows Version	Return Value
Windows 2000 Server	0x00000002
Windows Server 2003	0x00000004
Windows Server 2008	0x00000006
Windows Server 2008 R2	0x00000006
Windows Server 2012	0x00000006
Windows Server 2012 R2	0x00000006

<38> [Section 3.1.4.1.2](#): The RPC interface version has remained constant since Windows NT Server 4.0. Windows 2000 Server adds new methods to the same RPC interface. Also, Windows 2000 Server supports hosting of at most one DFS namespace. Hence, applications could potentially handle version differences by using the returned version information.

<39> [Section 3.1.4.1.2](#): A Windows NT Server 4.0 can host at most one DFS namespace. Windows Server 2003, except for Windows Server 2003 Standard Edition, supports hosting of more than one DFS namespace per server. In default configurations, Windows Server 2003 Standard Edition supports hosting of at most one DFS namespace per server.

<40> [Section 3.1.4.1.2](#): Windows clients use the returned value to determine when to call [NetrDfsEnum](#) versus [NetrDfsEnumEx](#). For more information, see section [3.2.4.1.4](#).

<41> [Section 3.1.4.1.2](#): Windows Server 2003 with SP1, Windows Server 2003 SP2, Windows Server 2003 R2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 support [NetrDfsMove \(Opnum 6\)](#).

<42> [Section 3.1.4.1.3](#): Windows 2000 Server does not support a domain-based DFS namespace in the [NetrDfsAdd](#) method.

<43> [Section 3.1.4.1.3](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not verify whether link targets exist. Windows 2000 and Windows NT 4.0 do verify whether link targets exist unless `DFS_RESTORE_VOLUME` is specified.

<44> [Section 3.1.4.1.3](#): Windows 2000 and Windows NT 4.0 do use this test.

<45> [Section 3.1.4.1.3](#): Windows 2000 Server requires that the `DFS_ADD_VOLUME` flags parameter be specified when a new link is being created; Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not require this.

Windows servers check whether a folder or a file that has the same name as the link appears in the object store under the root and take the following actions:

- If no folder or file exists, create the link folder.
- If an empty folder with the same name as the link exists, do not create a new link folder.
- If a non-empty folder or a file with the same name as the link exists, rename the non-empty folder or the file to `DFS.GUIDLinkName`, and create a new link folder. An example of a renamed non-empty folder or file is `DFS.cf13c05f-5c10-4879-9acb-04ced8f46c7aTemplates`, where `cf13c05f-5c10-4879-9acb-04ced8f46c7a` is the *GUID* and `Templates` is the *LinkName*.

- Set the reparse point to the leaf folder of the link path. For example, if the link path is HR\Documents, set the reparse point to the Documents folder.

<46> [Section 3.1.4.1.3](#): The **msDFS-Commentv2** field in the Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 metadata is updated with the value that is passed on as input.

<47> [Section 3.1.4.1.3](#): **NetrDfsAdd** in Windows 2000 Server supports only a stand-alone DFS namespace. Windows 2000 Server returns ERROR\_NOT\_SUPPORTED (0x00000032) if **NetrDfsAdd** is called on a domain-based DFS namespace.

<48> [Section 3.1.4.1.3](#): In Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2, **NetrDfsAdd** supports both stand-alone and domain-based DFS namespaces.

<49> [Section 3.1.4.1.4](#): Windows 2000 Server does not support a domain-based DFS namespace in the **NetrDfsRemove** method.

<50> [Section 3.1.4.1.4](#): This method does not support domain-based DFS namespaces in Windows 2000 Server; **NetrDfsRemove2** is used instead. Windows 2000 Server will return ERROR\_NOT\_SUPPORTED (0x00000032) if **NetrDfsRemove** is called on a domain-based DFS namespace.

<51> [Section 3.1.4.1.4](#): In Windows Server 2003, the **NetrDfsRemove** method is functionally equivalent to **NetrDfsRemove2**.

<52> [Section 3.1.4.1.5](#): Windows 2000, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 allow the target state of a root target or a link target to be set to either DFS\_STORAGE\_STATE\_ONLINE or DFS\_STORAGE\_STATE\_OFFLINE. Windows Server 2003 does not allow the target state of a root target to be set to DFS\_STORAGE\_STATE\_OFFLINE.

Windows 2000 Server does not support DFS\_VOLUME\_STATE\_RESYNCHRONIZE for the **State** field of **DFS\_INFO 101** for a **Level** parameter value of 101.

<53> [Section 3.1.4.1.5](#): Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 allow setting the target state of a root target or a link target to either DFS\_STORAGE\_STATE\_ONLINE or DFS\_STORAGE\_STATE\_OFFLINE. Windows Server 2003 does not allow setting the target state of a root target to DFS\_STORAGE\_STATE\_OFFLINE.

<54> [Section 3.1.4.1.5](#): A *Level* value of 102 is not supported on Windows NT Server 4.0.

*Level* parameter values 103-106 are not supported on Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003 RTM.

*Level* parameter values 107 and 150 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003.

<55> [Section 3.1.4.1.5](#): On Windows NT Server 4.0 and Windows 2000 Server, the server returns error code ERROR\_INVALID\_LEVEL.

<56> [Section 3.1.4.1.5](#): Windows 2000 Server does not support a domain-based DFS namespace in the **NetrDfsSetInfo** method.

<57> [Section 3.1.4.1.5](#): The **NetrDfsSetInfo** method supports only the stand-alone DFS namespace on Windows 2000 Server. **NetrDfsSetInfo** supports both stand-alone and domain-based DFS namespaces on Windows Server 2003, Windows Server 2008, Windows Server 2008 R2,

Windows Server 2012, and Windows Server 2012 R2. *Level* parameter values 103, 104, 105, and 106 are valid only on Windows Server 2003 with SP1, Windows Server 2003 SP2, Windows Server 2003 R2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2. *Level* parameter values 107 and 150 are supported only on Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

[<58> Section 3.1.4.1.6:](#) This level is supported only on Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

[<59> Section 3.1.4.1.6:](#) Level 4 is not supported in Windows NT Server 4.0.

Levels 5, 6, and 7 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003 RTM. Level 7 is supported for domain-based DFS only. It is used to determine whether the DFS metadata of the namespace has changed.

Level 50 and 150 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003.

[<60> Section 3.1.4.1.6:](#) On Windows NT Server 4.0 and Windows 2000 Server, the server returns error code `ERROR_INVALID_LEVEL`.

[<61> Section 3.1.4.1.6:](#) For a stand-alone namespace in Windows, metadata size is the sum of the following:

- Size of the name of all the keys in the namespace (all keys under the DFS root key in registry)
- Size of the values under each key
- Size of the data of each value

[<62> Section 3.1.4.1.7:](#) Level 4 is not supported in Windows NT Server 4.0.

Levels 5 and 6 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003 RTM.

Levels 8 and 9 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003.

Level 200 is not supported in Windows NT Server 4.0 and is only valid on a domain controller (DC).

Level 300 is not supported in Windows NT Server 4.0, or Windows 2000 Server.

[<63> Section 3.1.4.1.7:](#) On Windows NT Server 4.0 and Windows 2000 Server, the server returns error code `ERROR_INVALID_LEVEL`.

[<64> Section 3.1.4.1.7:](#) On return, the `DfsEnum`'s **DfsInfoContainer** member contains an array of information structures specific to the *Level* requested by the caller. In Windows 2000 Server, Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2, the number of entries to return in the enumeration is calculated by dividing *PrefMaxLen* by the size of the **Level**-specific information structure, using integer division. If the result is zero, one entry is returned.

This calculation is performed on the server by using the native size of the specified information structure on the server's architecture. As all of the **Level**-specific information structures contain pointers, such as the **DFS\_INFO\_1 EntryPath** member, this condition has an important effect. Because the size of a pointer on a 32-bit architecture differs as compared to a 64-bit architecture, the returned number of entries may be higher or lower than that implied by the native architecture of the client, depending on the native architecture of the server.

[<65> Section 3.1.4.1.7:](#) Windows servers use the *ResumeHandle* parameter as an index into the collection of enumerable items. Due to intervening or concurrent updates, a resumed enumeration may return non-unique or incomplete results.

[<66> Section 3.1.4.1.7:](#) This method is supported only by Windows NT Server 4.0, Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

[<67> Section 3.1.4.1.7:](#) The **NetrDfsEnum** method is used only with Windows 2000 Server because there is no parameter to specify the name of a DFS namespace. In Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2, the DFS server can successfully process this method if it is hosting only one DFS namespace root target.

[<68> Section 3.1.4.1.8:](#)

Windows Server 2003 with SP1, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not allow the following:

- The Unicode code points 0x0000 through 0x001F, 0x0022 ("), 0x002A (\*), 0x002F (/), 0x003A (:), 0x003C (<), 0x003E (>), 0x003F (?), or 0x007C (|).
- The relative path elements "." or "..".

[<69> Section 3.1.4.1.8:](#) Windows servers perform DFS link move operations atomically for domainv1-based DFS namespaces. Move operations in stand-alone DFS namespaces and domainv2-based DFS namespaces are not atomic.

[<70> Section 3.1.4.1.8:](#) If there is a conflict between an existing file and a pathname component in the destination path or DFS link of a move operation, Windows servers rename the existing file by appending a ".{GUID}" to the file name, where "{GUID}" is a newly generated GUID.

[<71> Section 3.1.4.1.8:](#) Windows servers remove intermediate directories in the pathname of a source DFS link if they are empty.

[<72> Section 3.1.4.1.8:](#) This method is supported only on Windows Server 2003 with SP1, Windows Server 2003 SP2, Windows Server 2003 R2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

[<73> Section 3.1.4.1.9:](#) This method is supported only on Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

[<74> Section 3.1.4.1.10:](#) This method is supported only on Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

[<75> Section 3.1.4.1.10:](#) Windows does not fail calls that specify reserved bits.

[<76> Section 3.1.4.1.10:](#) Windows does not support DFS\_FORCE\_REMOVE on member servers.

[<77> Section 3.1.4.1.10:](#) Windows removes local information related to the root.

[<78> Section 3.1.4.1.11:](#) This method is supported only on Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

[<79> Section 3.1.4.2.1:](#) Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 ignore the *DcName* parameter.

[<80> Section 3.1.4.2.1:](#) The *ppRootList* parameter is not referenced in Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2. On success in Windows 2000, the RPC call returns a list of the remaining root targets of the DFS namespace .

To support down-level compatibility with Windows 2000, Windows clients issue a [NetrDfsSetDcAddress](#) to each root target listed in *ppRootList* by specifying the name of the PDC used for the *DcName* parameter, the NET\_DFS\_SETDC\_INIT\_PKT and NET\_DFS\_SETDC\_TIMEOUT flags for the *Flags* parameter, and a value of 0x00001C20 (7,200 seconds or 2 hours) for the *Timeout* parameter.

<81> [Section 3.1.4.2.1](#): This method is supported only by Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

<82> [Section 3.1.4.2.1](#): This method supports both stand-alone DFS namespaces and domain-based DFS namespaces in Windows 2000 Server, Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

The DFS\_RESTORE\_VOLUME bit of the *Flags* parameter is used only with Windows 2000 Server.

Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 ignore the *DcName* and *ppRootList* parameters.

To support down-level compatibility with Windows 2000 Server, Windows clients issue [NetrDfsSetDcAddress](#) to each root target listed in *ppRootList*. [NetrDfsSetDcAddress](#) specifies the name of the PDC that is used for the *DcName* parameter, and the NET\_DFS\_SETDC\_INIT\_PKT and NET\_DFS\_SETDC\_TIMEOUT flags for the *Flags* parameter. [NetrDfsSetDcAddress](#) also specifies a value of 0x00001C20 (7,200 seconds or 2 hours) for the *Timeout* parameter.

<83> [Section 3.1.4.2.1](#): Windows NT Server 4.0 does not support this method.

<84> [Section 3.1.4.2.1](#): Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 do not verify whether link targets exist. Windows 2000 Server and Windows NT 4.0 do verify whether link targets exist, unless DFS\_RESTORE\_VOLUME is specified.

<85> [Section 3.1.4.2.1](#): Windows 2000 Server and Windows NT 4.0 do use this test.

<86> [Section 3.1.4.2.1](#): Windows 2000 Server requires that the *DFS\_ADD\_VOLUME Flags* parameter be specified when creating a new link; Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 do not.

Windows servers check whether a folder or a file that has the same name as the link appears in the object store under the root and take the following actions:

- If no folder or file exists, create the link folder.
- If an empty folder with the same name as the link exists, do not create a new link folder.
- If a non-empty folder or a file with the same name as the link exists, rename the non-empty folder or the file to DFS.*GUIDLinkName*, and create a new link folder. An example of a renamed non-empty folder or file is DFS.cf13c05f-5c10-4879-9acb-04ced8f46c7aTemplates, where cf13c05f-5c10-4879-9acb-04ced8f46c7a is the *GUID* and Templates is the *LinkName*.
- Set the reparse point to the leaf folder of the link path. For example, if the link path is HR\Documents, set the reparse point to the Documents folder.

<87> [Section 3.1.4.2.2](#): Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 ignore the *DcName* parameter.

<88> [Section 3.1.4.2.2](#): The *ppRootList* parameter is not referenced in Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2. In Windows 2000, a list of remaining root targets of the DFS namespace is returned when the RPC call succeeds.

To support down-level compatibility with Windows 2000, Windows clients issue a [NetrDfsSetDcAddress](#) to each root target listed in *ppRootList* by specifying the name of the PDC used for the *DcName* parameter, the `NET_DFS_SETDC_INIT_PKT` and `NET_DFS_SETDC_TIMEOUT` flags for the *Flags* parameter, and a value of `0x00001C20` (7,200 seconds or 2 hours) for the *Timeout* parameter.

<89> [Section 3.1.4.2.2](#): This method is supported only by Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

<90> [Section 3.1.4.2.2](#): This method supports both stand-alone DFS namespaces and domain-based DFS namespaces in Windows 2000 Server, Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

The *ppRootList* parameter is not used in Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

To support down-level compatibility with Windows 2000 Server, Windows clients issue a [NetrDfsSetDcAddress](#) to each root target listed in *ppRootList* by specifying the name of the PDC used for the *DcName* parameter, the `NET_DFS_SETDC_INIT_PKT` and `NET_DFS_SETDC_TIMEOUT` flags for the *Flags* parameter, and a value of `0x00001C20` (7,200 seconds or 2 hours) for the *Timeout* parameter.

<91> [Section 3.1.4.2.2](#): Windows NT Server 4.0 does not support this method.

<92> [Section 3.1.4.2.3](#): While Windows 2000 Server can host at most one root target, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 can host more than one root target on the same server. This precludes meaningful use of the [NetrDfsEnum](#) method by Windows Server 2003 and Windows Server 2008 because [NetrDfsEnum](#) does not have a parameter to specify the DFS namespace of interest. Hence, the [NetrDfsEnumEx](#) method is used on Windows Server 2003 and Windows Server 2008.

<93> [Section 3.1.4.2.3](#): Windows NT Server 4.0 does not support the [NetrDfsEnumEx](#) method.

<94> [Section 3.1.4.2.3](#): Level 4 is not supported in Windows NT Server 4.0.

Levels 5 and 6 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003.

Levels 8 and 9 are not supported in Windows NT Server 4.0, Windows 2000 Server, or Windows Server 2003.

Level 200 is not supported in Windows NT Server 4.0, and it is only valid on a domain controller (DC).

Level 300 is not supported in Windows NT Server 4.0 or Windows 2000 Server.

<95> [Section 3.1.4.2.3](#): On Windows NT Server 4.0 and Windows 2000 Server, the server returns error code `ERROR_INVALID_LEVEL`.

<96> [Section 3.1.4.2.3](#): On return, the `DfsEnum`'s **DfsInfoContainer** member contains an array of information structures specific to the *Level* requested by the caller. In Windows 2000 Server, Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2, the number of entries to return in the enumeration is calculated by dividing *PrefMaxLen* by the size of the **Level**-specific information structure, using integer division. If the result is zero, one entry is returned.

This calculation is performed on the server by using the native size of the given information structure on the server's architecture. As all of the **Level** specific information structures contain pointers, such as the **DFS\_INFO\_1 EntryPath** member, this condition has an important effect. Because the size of a pointer on a 32-bit architecture differs as compared to a 64-bit architecture, the returned number of entries may be higher or lower than that implied by the native architecture of the client, depending on the native architecture of the server.

<97> [Section 3.1.4.2.3:](#) Windows servers use the *ResumeHandle* parameter as an index into the collection of enumerable items. Due to intervening or concurrent updates, a resumed enumeration may return non-unique or incomplete results.

<98> [Section 3.1.4.2.3:](#) To be backward-compatible with the **NetrDfsEnum** method, in this case the **NetrDfsEnumEx** method in Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 ignores the <ServerName> in *DfsEntryPath* and returns the required information for the specified Level based on the namespace it hosts.

The **NetrDfsEnum** method is used only with Windows 2000 Server because there is no parameter to specify the name of a DFS namespace. In Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2, the DFS server can successfully process this method if it is hosting only one DFS namespace root target.

<99> [Section 3.1.4.2.4:](#) Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 ignore the *DcName* parameter.

<100> [Section 3.1.4.2.4:](#) Windows 2000, Windows Server 2008, and Windows Server 2008 R2 allow the target state of a root target or a link target to be set to either `DFS_STORAGE_STATE_ONLINE` or to `DFS_STORAGE_STATE_OFFLINE`. Windows Server 2003 does not allow the target state of a root target to be set to `DFS_STORAGE_STATE_OFFLINE`.

Windows 2000 Server does not support `DFS_VOLUME_STATE_RESYNCHRONIZE` for the **State** field of **DFS\_INFO\_101** for a *Level* parameter value of 101.

<101> [Section 3.1.4.2.4:](#) Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 allows the target state of a root target or a link target to be set to either `DFS_STORAGE_STATE_ONLINE` or to `DFS_STORAGE_STATE_OFFLINE`. Windows Server 2003 does not allow the target state of a root target to be set to `DFS_STORAGE_STATE_OFFLINE`.

<102> [Section 3.1.4.2.4:](#) Level 102 is not supported in Windows NT Server 4.0.

Levels 103-106 are not supported in Windows NT Server 4.0, Windows 2000 Server or Windows Server 2003 RTM.

Levels 107 and 150 are not supported in Windows NT Server 4.0, Windows 2000 Server or Windows Server 2003.

<103> [Section 3.1.4.2.4:](#) On Windows NT Server 4.0 and Windows 2000 Server, the server returns error code `ERROR_INVALID_LEVEL`.

<104> [Section 3.1.4.2.4:](#) The *ppRootList* parameter is not referenced in Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2. In Windows 2000, a list of remaining root targets of the DFS namespace is returned when the RPC call succeeds.

To support down-level compatibility with Windows 2000, Windows clients issue a **NetrDfsSetDcAddress** to each root target listed in *ppRootList* by specifying the name of the PDC used for the *DcName* parameter, the `NET_DFS_SETDC_INIT_PKT` and `NET_DFS_SETDC_TIMEOUT`

flags for the *Flags* parameter, and a value of 0x00001C20 (7,200 seconds or 2 hours) for the *Timeout* parameter.

<105> [Section 3.1.4.2.4](#): This method is supported only on Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

<106> [Section 3.1.4.2.4](#): Windows 2000, Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 support both stand-alone and domain-based DFS namespaces for [NetrDfsSetInfo2 \(Opnum 22\)](#).

<107> [Section 3.1.4.2.4](#): Windows NT Server 4.0 does not support this method.

<108> [Section 3.1.4.3.1](#): Windows 2000, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 ignore this parameter and use the local **NetBIOS host name** instead.

<109> [Section 3.1.4.3.1](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 ignore the *ConfigDN* parameter.

<110> [Section 3.1.4.3.1](#): No information is returned through the *ppRootList* parameter on Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

To support down-level compatibility with Windows 2000 Server, Windows clients issue a [NetrDfsSetDcAddress \(Opnum 17\)](#) method to each root target listed in *ppRootList* by specifying the name of the PDC used for the *DcName* parameter, the NET\_DFS\_SETDC\_INIT\_PKT and NET\_DFS\_SETDC\_TIMEOUT flags for the *Flags* parameter, and a value of 0x00001C20 (7,200 seconds or 2 hours) for the *Timeout* parameter.

Windows NT Server 4.0 does not support this method.

<111> [Section 3.1.4.3.1](#): No information is returned through the *ppRootList* parameter on Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2. To support down-level compatibility with Windows 2000, Windows clients issue a [NetrDfsSetDcAddress \(Opnum 17\)](#) method to each root target listed in *ppRootList* specifying the name of the PDC used for the *DcName* parameter, the NET\_DFS\_SETDC\_INIT\_PKT and the NET\_DFS\_SETDC\_TIMEOUT flags for the *Flags* parameter, and a value of 0x00001C20 (7,200 seconds or 2 hours) for the **Timeout** parameter. Windows NT 4.0 does not support this method.

<112> [Section 3.1.4.3.2](#): Windows NT Server 4.0 does not support the [NetrDfsRemoveFtRoot](#) method.

<113> [Section 3.1.4.3.2](#): Windows does not fail calls that specify reserved bits.

<114> [Section 3.1.4.3.2](#): The *ppRootList* parameter is not referenced on Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2. On Windows 2000, a list of remaining root targets of the DFS namespace is returned when the RPC call succeeds.

To support down-level compatibility with Windows 2000, Windows clients issue a [NetrDfsSetDcAddress \(Opnum 17\)](#) to each root target listed in *ppRootList* by specifying the name of the PDC used for the *DcName* parameter, the NET\_DFS\_SETDC\_INIT\_PKT and NET\_DFS\_SETDC\_TIMEOUT flags for the *Flags* parameter, and a value of 0x00001C20 (7,200 seconds or 2 hours) for the *Timeout* parameter.

<115> [Section 3.1.4.3.2](#): Windows does not support DFS\_FORCE\_REMOVE on member servers.

<116> [Section 3.1.4.3.2](#): Windows does not remove local information related to the root.

<117> [Section 3.1.4.3.2](#): Windows servers do not remove the object of a domain-based DFS namespace if the last DFS root target is being removed. Windows clients remove the object of the DFS namespace on successful return from this method.

<118> [Section 3.1.4.4.1](#): The [NetrDfsAddStdRoot \(Opnum 12\)](#) method can also be used for clustered DFS with Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2.

<119> [Section 3.1.4.4.1](#): Windows NT Server 4.0 does not support this method.

<120> [Section 3.1.4.4.1](#): Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 return this error code for the described condition.

<121> [Section 3.1.4.4.1](#): Windows 2000 returns this error code for the described condition.

<122> [Section 3.1.4.4.2](#): Windows NT Server 4.0 does not support the [NetrDfsRemoveStdRoot](#) method.

<123> [Section 3.1.4.4.3](#): The [NetrDfsAddStdRootForced](#) method is used to create a clustered DFS namespace in Windows 2000 Server. This call allows an offline share to host the DFS root.

<124> [Section 3.1.4.4.3](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not support the [NetrDfsAddStdRootForced](#) method. Use the [NetrDfsAddStdRoot \(Opnum 12\)](#) method instead.

<125> [Section 3.1.4.4.3](#): Windows NT Server 4.0 does not support the [NetrDfsAddStdRootForced \(Opnum 15\)](#) method.

<126> [Section 3.1.4.5.1](#): Windows NT Server 4.0 does not support the [NetrDfsGetDcAddress](#) method.

<127> [Section 3.1.4.5.1](#): Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 ignore the *ServerName* parameter.

<128> [Section 3.1.4.5.1](#): Windows clients ignore the value returned in the *DcName* parameter; Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 return a blank name.

<129> [Section 3.1.4.5.1](#): Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 always return FALSE in the *IsRoot* parameter. While Windows Server 2003 Standard Edition supports the ability to host only one DFS namespace, it returns FALSE in the *IsRoot* parameter even when it is hosting a DFS namespace.

The client-side wrapper of the [NetrDfsAddFtRoot \(Opnum 10\)](#) RPC method in Windows 2000 Server, Windows XP, Windows Server 2003, Windows Vista, Windows Server 2008, and Windows Server 2008 R2 uses the [NetrDfsGetDcAddress](#) method to determine whether the server to which the RPC is to be issued is already hosting a DFS namespace. If the value returned in the *IsRoot* parameter is TRUE, the [NetrDfsAddFtRoot \(\)](#) method fails at the client. This is meant for Windows 2000 Server, which supports the ability to host at most one DFS namespace. This is why Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 always return FALSE for the *IsRoot* parameter.

<130> [Section 3.1.4.5.1](#): In Windows 2000 Server, the default time-out value is 2 hours. This value can be overridden by calling [NetrDfsSetDcAddress \(Opnum 17\)](#).

<131> [Section 3.1.4.5.1](#): This method is supported only by Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2.

<132> [Section 3.1.4.5.2](#): Windows NT Server 4.0 does not support the [NetrDfsSetDcAddress](#) method.

<133> [Section 3.1.4.5.2](#): Windows does not fail the call if reserved bits are specified.

<134> [Section 3.1.4.5.2](#): Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 implement it as a method with no effect that returns ERROR\_SUCCESS. Windows Server 2012 and Windows Server 2012 R2 do not implement this method.

<135> [Section 3.1.4.5.2](#): To support down-level compatibility with Windows 2000 Server, Windows clients issue a [NetrDfsSetDcAddress \(Opnum 17\)](#) to each DFS root target returned in the *ppRootList* parameter from an invocation of [NetrDfsAdd2 \(Opnum 19\)](#), [NetrDfsRemove2 \(Opnum 20\)](#), [NetrDfsSetInfo2 \(Opnum 22\)](#), [NetrDfsAddFtRoot \(Opnum 10\)](#), or [NetrDfsRemoveFtRoot \(Opnum 11\)](#) methods. [NetrDfsSetDcAddress \(Opnum 17\)](#) specifies the name of the PDC used for the *DcName* parameter, the NET\_DFS\_SETDC\_INIT\_PKT and the NET\_DFS\_SETDC\_TIMEOUT flags for the *Flags* parameter, and a value of 0x00001C20 (7,200 seconds or 2 hours) for the *Timeout* parameter.

<136> [Section 3.2.3](#): Windows 2000, Windows XP, Windows Server 2003, Windows Vista, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 clients create a separate binding for every method invocation.

<137> [Section 3.2.4.1.1](#): Windows NT 4.0 and Windows 2000 Server never reissue the [NetrDfsAdd2](#) method.

<138> [Section 3.2.4.1.2](#): Windows NT 4.0 and Windows 2000 Server never reissue the [NetrDfsRemove2](#) method.

<139> [Section 3.2.4.1.3](#): Windows NT 4.0 and Windows 2000 Server never reissue the [NetrDfsSetInfo2](#) method.

<140> [Section 3.2.4.1.4](#): For level values other than 200, Windows XP, Windows Server 2003, Windows Vista, Windows Server 2008, Windows 7, Windows Server 2008 R2, Windows 8, Windows Server 2012, Windows 8.1, and Windows Server 2012 R2 clients first call the [NetrDfsManagerGetVersion](#) method. If the returned version value is 0x00000004 or greater, the client calls the [NetrDfsEnumEx](#) method. If the returned version value is less than 0x00000004, the client calls the [NetrDfsEnum](#) method. For level 200, Windows XP, Windows Server 2003, Windows Vista, Windows Server 2008, Windows 7, Windows Server 2008 R2, Windows 8, Windows Server 2012, Windows 8.1, and Windows Server 2012 R2 clients always call the [NetrDfsEnumEx](#) method on the PDC.

<141> [Section 3.2.4.1.4](#): The Windows 2000 Server client does not call either [NetrDfsEnum](#) or [NetrDfsEnumEx](#) for level 200; rather, it determines the list of domain-based DFS namespaces through an LDAP query directly on the DFS configuration container.

<142> [Section 3.2.4.1.4](#): Windows clients rely on human operators to detect inconsistent results in displayed output and to request a new enumeration.

<143> [Section 3.2.4.3.1](#): Only Windows 2000 Server returns other existing DFS root targets of the DFS namespace in the *ppRootList* parameter. Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not return any information in the *ppRootList* parameter.

<144> [Section 3.2.4.3.1](#): Windows clients fail the [NetrDfsAddFtRoot](#) operation on the client if an IP address is given as the *ServerName* parameter. This is because Windows clients attempt to use the *ServerName* parameter as the security principal when updating the ACL of the object of a domain-based DFS namespace. Because **AD** does not permit an IP address to be used as a security principal, a Windows client will fail on the ACL update before sending the [NetrDfsAddFtRoot](#) request message.

<145> [Section 3.2.4.3.2](#): Windows NT Server 4.0 does not support the [NetrDfsRemoveFtRoot](#) method.

<146> [Section 3.2.4.3.2](#): Only Windows 2000 Server returns other existing DFS root targets of the DFS namespace in the *ppRootList* parameter. Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not return any information in the *ppRootList* parameter.

<147> [Section 3.3.4](#): Windows allows DCs to be DFS root targets.

<148> [Section 3.3.4.2.1](#): Level parameter value 200 is not supported in Windows NT 4.0 and only valid on a domain controller (DC).

<149> [Section 3.3.4.3.2](#): Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2 do not support this method and will fail with `ERROR_NOT_SUPPORTED (0x00000032)`.

On a successful call to the [NetrDfsAddFtRoot](#) or [NetrDfsRemoveFtRoot](#) methods, Windows clients call the [NetrDfsFlushFtTable](#) method on the PDC of the domain of the DFS root target server. For more information, see sections [3.2.4.3.1](#) and [3.2.4.3.2](#).

This method is not supported on Windows NT Server 4.0.

<150> [Section 5.1](#): Windows servers use the RPC Protocol to retrieve the identity of the caller, as specified in [\[MS-RPCE\]](#) section 3.3.3.4.3. The server uses the underlying Windows security subsystem to determine the permissions for the caller. If the caller does not have the required permissions to execute a specific method, the method call fails with `ERROR_ACCESS_DENIED (0x00000005)`.

## 8 Appendix C: XML Schema of XML Document Stored in msDFS-TargetListv2 Attribute

For more information about XML and XML schemas, see [\[XML\]](#) and [\[XMLSCHEMA\]](#), respectively.

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
            xmlns="http://schemas.microsoft.com/dfs/2007/03"
            targetNamespace="http://schemas.microsoft.com/dfs/2007/03"
            elementFormDefault="qualified">
  <xsd:annotation>
    <xsd:documentation xml:lang="en">
      Schema document for DFS targets (root or link) for use by the
      domainV2 code in the DFS service. An XML document conforming
      to this schema is stored as the value of an attribute of the
      LDAP entry corresponding to a DFS namespace root or DFS link
      and contains the information on the targets of that DFS
      namespace root or DFS link.

      Conventions:
      - There is a target namespace for this schema document.
        This means instances instances must also declare the same
        namespace for them to be validated using this schema.
      - The elementFormDefault attribute is set to qualified so
        that an instance conforming to this schema can set this
        schema document's namespace as its default namespace and
        have all all unqualified element-type names be considered
        part of the default namespace.
      - Data are in elements, metadata in attributes.

    </xsd:documentation>

## 9 Change Tracking

This section identifies changes that were made to the [MS-DFSNM] protocol document between the November 2013 and February 2014 releases. Changes are classified as New, Major, Minor, Editorial, or No change.

The revision class **New** means that a new document is being released.

The revision class **Major** means that the technical content in the document was significantly revised. Major changes affect protocol interoperability or implementation. Examples of major changes are:

- A document revision that incorporates changes to interoperability requirements or functionality.
- The removal of a document from the documentation set.

The revision class **Minor** means that the meaning of the technical content was clarified. Minor changes do not affect protocol interoperability or implementation. Examples of minor changes are updates to clarify ambiguity at the sentence, paragraph, or table level.

The revision class **Editorial** means that the formatting in the technical content was changed. Editorial changes apply to grammatical, formatting, and style issues.

The revision class **No change** means that no new technical changes were introduced. Minor editorial and formatting changes may have been made, but the technical content of the document is identical to the last released version.

Major and minor changes can be described further using the following change types:

- New content added.
- Content updated.
- Content removed.
- New product behavior note added.
- Product behavior note updated.
- Product behavior note removed.
- New protocol syntax added.
- Protocol syntax updated.
- Protocol syntax removed.
- New content added due to protocol revision.
- Content updated due to protocol revision.
- Content removed due to protocol revision.
- New protocol syntax added due to protocol revision.
- Protocol syntax updated due to protocol revision.
- Protocol syntax removed due to protocol revision.

- Obsolete document removed.

Editorial changes are always classified with the change type **Editorially updated**.

Some important terms used in the change type descriptions are defined as follows:

- **Protocol syntax** refers to data elements (such as packets, structures, enumerations, and methods) as well as interfaces.
- **Protocol revision** refers to changes made to a protocol that affect the bits that are sent over the wire.

The changes made to this document are listed in the following table. For more information, please contact [dochelp@microsoft.com](mailto:dochelp@microsoft.com).

Section	Tracking number (if applicable) and description	Major change (Y or N)	Change type
<a href="#">2.1 Transport</a>	Clarified that a link target can reside on an accessible server.	Y	Content updated.
<a href="#">3.1.4.1.3 NetrDfsAdd (Opnum 1)</a>	Updated product behavior note on NetrDfsAdd support for a domain-based DFS namespace.	Y	Product behavior note updated.
<a href="#">3.1.4.1.4 NetrDfsRemove (Opnum 2)</a>	Updated product behavior note on NetrDfsRemove support for a domain-based DFS namespace.	Y	Product behavior note updated.
<a href="#">3.1.4.4.1 NetrDfsAddStdRoot (Opnum 12)</a>	Updated product behavior note on the DFS namespace specified by the ServerName and RootShare parameters.	Y	Product behavior note updated.
<a href="#">3.2.4.1.1 NetrDfsAdd (Opnum 1)</a>	Updated product behavior note to clarify the cases in which the NetrDfsAdd2 method is not reissued.	Y	Product behavior note updated.
<a href="#">3.2.4.1.2 NetrDfsRemove (Opnum 2)</a>	Updated product behavior note to clarify the cases in which the NetrDfsRemove2 method is not reissued.	Y	Product behavior note updated.
<a href="#">3.2.4.1.3 NetrDfsSetInfo (Opnum 3)</a>	Updated product behavior note to clarify the cases in which the NetrDfsSetInfo2 method is not reissued.	Y	Product behavior note updated.
